INDUSTRIAL HYGIENE PROBLEMS IN THE UNITED STATES

CHAIRMAN'S ADDRESS

R R SAYERS, MD

WASHINGTON, D C

Industrial hygiene has been defined as that branch of preventive medicine which has to do with the protection of health of the industrial population. It is much broader than the consideration of specific occupational diseases.

Occupational disease is a difficult term to define, for, in addition to the medical difficulties in determining the relationship between the associated industry and the disease, the difficulties are further increased by the fact that occupational diseases are often legally defined, and these legal definitions vary from state to state or from country to country. Many states have schedules of occupational diseases, and no other diseases can be considered as occupational in that particular state. In the Act on Occupational Diseases, recently passed in the U. S., it is stated "In this Act the term 'occupational disease' means the disease arising out of and in the course of the employment. Ordinary diseases of life to which the general public is exposed outside of the employment shall not be compensable, except where the said disease follows as an incident of an occupational disease as defined."

These definitions may be quite limited, and from the standpoint of preventive medicine inadequate, even though they may be necessary legally and administratively.

The objective of industrial hygiene, in addition to the control of specific occupational diseases, is to reduce the incidence in occupational increase in those diseases common to adults in general. Industrial hygiene deals with problems of occupational poisons and dusts, ventilation, temperature and humidity, light, the noises and nuisances, cleanliness and plant sanitation, overcrowding, hours of labor, rest periods and fatigue, child labor, women in industry, medical and nursing services, physical examinations, communicable diseases in a factory, and personal hygiene. From this aspect, industrial hygiene is nearly as broad as preventive medicine.

Before undertaking the control of industrial health hazards, it seems logical that knowledge be obtained as to where, when and how they occur. To secure such information, it has been found helpful to study the morbidity and mortality statistics of industrial workers and to make preliminary plant studies to locate the potential industrial hygiene problems, and medical and

engineering surveys, together with necessary laboratory research, in which all data pertaining to the particular problem are secured and correlated.

According to the census of 1930, about 49 million persons were actively employed in the United States. Of this number about 15 million were employed in the manufacturing, mechanical and mineral industries. In these industries there are more than 900 occupations that have been considered potentially hazardous to health. From the census data the distribution may be had of the workers by states and by industries, as building, chemical, clay, glass, iron and steel, or mineral production. These data are useful in that they show where studies can profitably be undertaken. Additional data can be obtained from statistical sources, and while the value of these is lessened by inaccuracies in occupational analysis and cause of death and by variation in reporting, some indication of the relative risk in various occupations is afforded. In the study of Dr. Louis Dublin the effects of occupational environment on three and one-half million wage earners insured by the Metropolitan Life Insurance Company from 1922 to 1924 were evaluated. This study showed, among other things, that the industrial worker at the age of 20 had an expectation of life of forty-two years, as compared with forty-nine years for the nonindustrial worker. Dr. Dublin concludes that, while hereditary differences may play some part, probably the most important factors are the conditions incidental to industrial employment. The value of mortality statistics is found to be limited in that they afford no information concerning illnesses that do not result in death. When supplemented by records of sickness it is possible to determine far more accurately the effect of any particular environment or process.

Since 1917 the U. S. Public Health Service, in cooperation with a number of industries, has been analyzing and reporting on the frequency of sickness causing disability of more than a week among approximately 160,000 male workers. The annual reports on this group contain the frequency rates for specific diseases. In one industry a high pneumonia rate was found. Factors apart from the working conditions, such as seasonal variation, influenza epidemics, economic status of the workers, their age and nationality, addiction to alcohol, and general prevalence of pneumonia in the community, were insufficient to account for the excess frequency of pneumonia. Analysis according to the conditions showed that the groups exposed intermittently to high temperatures, unsheltered work or drafty conditions experienced the disease and accounted for the major part of the excess for all groups under study.

In ascertaining the effect of occupation on the health of workers in dusty trades over a period of several years and causing an absence of more than a week, it was found that the incidence of respiratory diseases

was about three times as great in granite cutting as in general manufacturing, and that the rate of pulmonary tuberculosis was about forty times as great.

Employees in the groups studied in soft coal mining, textile plants and other industries experienced rates in absences of eight days or longer due to respiratory diseases which were not much above the average for male industrial workers in general.

At present industry does not possess data concerning the incidence of specific diseases for given ages according to sex and by geographic areas correlated with occupations. From experience it has been found that the records of industrial sick benefit associations and group sickness insurance plans are the most accurate available. A comparison of the sickness rates in any given group with the average or expected rate will indicate whether there is an increase in incidence associated with a particular occupation, and whether further study is needed.

PRELIMINARY STUDIES

In the absence of definite industrial morbidity and mortality statistics, some conception of the extent of the problem may be secured by a preliminary survey

example, size of room, ventilation, illumination, facilities for cleanliness, and drinking water. As an example of using the data from this form, under item 1 the size of the workroom is given, under another (item 12) the workroom population at full production is shown. The observations are then compared with that which is considered good practice, and recommendations are made accordingly. An occupational analysis will show the number of persons in each occupation, and the number of activities in each occupation, also the number exposed to various conditions to be studied. Quantitative determinations are made of the particular health hazard in each activity. These exposures are correlated with the activities and occupations of the men, together with a study of their physical condition and their past and present illnesses, both the engineer and the physician being acquainted with the requirements of each occupation in each industry and with the exposure. It is possible thus to make recommendations as to measures for the elimination or control of the disease.

The engineering methods include isolation of the hazardous processes, ventilation, general and exhaust locally, and personal protective devices, such as respira-

No severe epidemics of influenza occurred during these years.

or study of the industrial establishment or establishments by one trained in industrial hygiene engineering. Such a preliminary survey or study should be of a type that will reveal the number of persons employed in the various occupations, the materials, processes and conditions associated with these occupations, and the welfare facilities afforded the workers in the plant. It must be emphasized, however, that the information obtained in such a study must not be interpreted as indicating in any manner that an exposure to an industrial condition or material necessarily implies injury to a workman but merely indicates the potentialities of the situation.

Such preliminary data, however, does not give quantitative information as to exposure from the point of view of possible systemic poisoning. This is determined by medical and engineering studies. Bloomfield and DallaValle¹ have discussed the method of engineering procedure.

In the engineering studies a record is made of the general environmental conditions in the workroom—for

tors, canister type masks, fresh air or hose type masks, protective clothing, suitable bathing facilities, and good housekeeping within the plant. This last is a most important control measure in industrial hygiene and is included in the industrial sanitation codes in many states and in the Safety Code for Industrial Sanitation in Manufacturing Establishments, approved by the American Standards Association and sponsored by the United States Public Health Service.

The medical control for the protection of the health of the industrial worker depends on knowledge of the industry and of the occupation and activities within each occupation, and physical examination of all persons, especially those exposed to substances or conditions hazardous to health. Such physical examinations should be performed by some impartial person or agency mutually acceptable to the employer and the employee. It should be kept in mind that the purpose of physical examinations is for the protection of the health of the individual examined and the health of other workers with whom he is associated, great care being taken to insure that such physical examinations shall not be used to the detriment of the worker.

¹ Bloomfield and DallaValle. The Determination and Control of Industrial Dust. Pub. Health Bull. 217.

Recently a number of state departments of health have shown interest in establishing divisions of bureaus of industrial hygiene, with the following functions in view

Administrative

- (a) Arrange for securing and investigating reports of occupational diseases to the state department of health
- (b) Secure reports of all diseases for which sick benefits are paid by industrial sick benefit organizations in the state department of health
- (c) Cooperate and provide a source of information for other state departments such as industry, labor, insurance and medical interests, or any agency interested in industrial hygiene
- (d) Educational program to acquaint industry and various groups interested as to the importance of the problem

Field Investigations

- (a) Preliminary survey to determine the scope and nature of the industrial hygiene problems in the state
- (b) Surveys by field personnel of plant conditions causing or suspected of causing occupational diseases in order that the department may advise or make recommendations for the control of existing or potential health hazard

It is believed that, if such bureaus are administered in a way to obtain the cooperation of the employer, employee, medical profession and other interested state departments such as labor, mines and insurance commissions to whom they should be of service the life of the industrial worker may be materially prolonged

Office of Industrial Hygiene and Sanitation U S Public Health Service

TRANSITORY SYNOVITIS OF THE HIP JOINT IN CHILDHOOD

JEROME G FINDER, M D

IOWA CITY

Transitory synovitis of the hip joint in childhood often remains unrecognized despite its relatively frequent occurrence. Usually the disease is erroneously diagnosed as tuberculosis of the hip, although the subsequent course and ultimate prognosis in the two conditions are vastly different. Other terms employed to designate this disease are *coxitis serosa seu simplex*, *coxitis fugitiva*, *coxitis ephemera*, *coxitis fugax*, *coxitis incertae causae* and *transitory arthritis of the hip joint*. Twenty-two cases have been recognized in this clinic since 1916, it is significant that since our attention has been focused on this syndrome the diagnosis has been made seven times in the past two years.

ETIOLOGY

Various factors have been indicated as responsible for the development of transitory synovitis of the hip joint. Butler¹ believes that infection, rather than trauma, is the chief cause. However, septic embolus, chemical toxins, mechanical-static imbalance, and climatological fluctuations have been blamed.² I am inclined to agree with Butler that an underlying, nonspecific infective focus is usually responsible. Since the disease process per se is not specific, any one of several factors may be the cause of the syndrome.

In ten of our cases, five different factors which might have even a very remote contributory effect were

recorded. In four instances, trauma resulting from a fall was held responsible. Muscular strain (tap dancing and track athletics), contagion (measles and scarlet fever) and infection (influenza and tonsillitis) each accounted for two cases. Granting that the factors named may have played an etiologic role, I am still at a loss in demonstrating a plausible cause in more than half (twelve) of the cases. Butler could find no obvious reason in thirteen cases in his series of twenty-two.

Age—The youngest patient observed in this series was 11 months old, the oldest 14 years of age, the average for the whole group was 5.4 years. Nineteen children (86 per cent) who were affected were 8 years old or younger, the remaining three (14 per cent) were in the age group of 9 to 14 inclusive. The average age in Butler's group was about 7 years.

Sex, Laterality, Race—Males and females were equally affected, Butler found males to predominate over females in the ratio of 17 to 5. No racial predisposition was noted. The right hip was involved twelve times, the left ten times.

SYMPTOMS

Prodromal—In eight cases the active symptoms were preceded by prodromal events but the variety of manifestations precludes their specificity. In one case slight pain in the thigh preceded the onset for ten days, in a second, intermittent pain was noted in the knee for eighteen months, in a third, some stiffness was felt in the back of the knee over a five months period. One child was restless and slept poorly for one week, another ushered in the disease with vomiting and fever for two days, and in one instance an intermittent fever of unknown source, rising to 103 F, was repeated over a period of three months. In one case, symptoms developed during convalescence from influenza, while in another the syndrome became evident during the third week of scarlet fever.

In view of the protean manifestations of the prodromal events one may feel that some of the introductory phrases were unrelated to the oncoming disease. On the other hand, intermittent fever, restlessness, vomiting or infection of some type, which so often precede such diseases as the acute exanthema, acute anterior poliomyelitis, meningitis, influenza or bronchopneumonia, may carry the same relation to acute synovitis that they bear to the better known nosologic entities. In short, although the prodromes are nonspecific in character, their premonitory significance, as in other diseases, should not be disregarded.

Onset—The onset is about equally divided between the acute (ten cases) and insidious (twelve cases) types. The same ratio holds true in the eight cases preceded by a prodromal stage. The latent period during which symptoms progressed before the patient was presented for medical advice, varied from one day to ten weeks. The average patient came to this clinic after symptoms had persisted for slightly less than one month. During this period seven patients had had previous treatment elsewhere, bed rest was prescribed in six cases for alleviation of prodromal or initial symptoms, in one instance, osteopathy was tried.

Symptoms—The symptoms, in order of their frequency, are limp, pain, frequently referred, night cries and restlessness. Limp occurred in seventeen cases (77 per cent). It varied from a slight alteration of the gait, especially when the patient was fatigued, to a marked abnormality of locomotion. Pain was a

² Belmonte, A. C. Over Voorhijgaande Goedaardige Coxitis (Coxitis Fugax). *Nederl. tijdschr. v. geneesk.* 75: 5197 (Oct. 17) 1931.

prominent feature in thirteen cases (59 per cent), it was marked in nine cases, dull in two, and of aching character in two. The pain was often (eight cases) referred to the knee (five times), occasionally along Poupert's ligament into the groin (two instances) and once to the anterior aspect of the thigh. Five children (22 per cent) were known to have night cries, in one case associated with marked restlessness.

Signs—Tenderness to pressure, limitation of hip motion, and positive Patrick and Trendelenburg signs were the chief objective signs. Tenderness to pressure, anteriorly over the head or neck of the femur of the affected hip joint, was elicited in nine (41 per cent) of the cases.

Limitation of motion was noted in many of the cases. The position of protection was the one most frequently assumed—adduction, flexion and internal rotation—or an incomplete combination of one or more of its component attitudes. Limited abduction was present seven times, incomplete extension in four cases, and decreased external rotation in four cases. Internal rotation was limited in five instances; adduction and flexion each once. Five patients exhibited restriction of all hip motions, rather markedly in one child and slightly in the other four. About one third of all cases (seven) showed no limitation of hip motion.

Leg Signs The Trendelenburg sign was positive in six cases (27 per cent). This may be explained by a relative insufficiency and atrophy of the gluteal muscles as the result of their stretching by the attitude of adduction spasm or contracture. The Patrick sign was positive in four children (17 per cent). This finding is congruous with the relatively frequent contracture in flexion, adduction and internal rotation.

General Data—Foci of Infection. Infected tonsils were present in five children, three of whom had subsequent tonsillectomies. In a single case of otitis media, drainage by a myringotomy was done.

Temperature A slight elevation of temperature was recorded in most cases but rose above 100 F. in only one fourth of the cases.

White Blood Count The white blood count, which was recorded in six cases, varied between 7,700 and 14,100 with a mean of 10,325.

Tuberculin Sensitivity In fifteen skin tests the tuberculin reaction was negative twelve times and positive twice, in one case the reaction was negative but became positive when repeated at a later date.

X-Ray Examination—It is self evident that the roentgenograms in these cases are negative for demonstrable lesions, since the pathologic changes are presumably confined to the synovial membrane. In some joints, however, a certain degree of bone resorption develops as a result of atrophy from disuse. An interpretation of erosion of the joint end should be made with reservation, because the irregularity may merely represent changes of the subchondral bone consistent with increased vascularity of the joint end, collateral to the synovitis.

TREATMENT

Treatment is essentially conservative. In one case, apparently past the acute stage, restricted activity sufficed to bring about complete subsidence of symptoms. Bed rest, averaging about 2.3 weeks, was prescribed for eleven children (50 per cent), to two of these, Buck's extension was added. In those cases which appeared to be more severe and were of longer duration, immobilization in a plaster-of-paris hip spica was

done for an average period of two months. Ten cases were treated by this method. The period of immobilization was elastic, however, it was chiefly determined by the celerity with which symptoms and muscle spasm disappeared. In one instance the cast was removed after three weeks, but in another child it was necessary to prolong cast treatment for almost five months.

The after-treatment consisted of physical therapy, especially radiant heat, massage and diathermy, followed by passive movement, and finally active exercises through the full range of hip joint motion. General hygienic measures were considered an integral part of the treatment. Foci of infection were eliminated, diet regulated, plenty of rest advised and vitamin-bearing tonics prescribed.

PROGNOSIS

In genuine cases of transitory synovitis of the hip joint, the outcome is uniformly good. Belmonte says "it is wonderful how, in several days, the functional disturbance completely disappears. After ten to fourteen days all complaints depart." Butler is likewise optimistic. He concludes "The prognosis of this transitory arthritis is excellent. A follow up of twenty-two cases for an average period of three years has been given." A similar prognostic inference is made by Bradford and Lovett,³ who say that "in children the diagnosis of synovitis of the hip joint should be made only when recovery has occurred in a few weeks and has proved permanent." In our series of twenty-two cases there was complete cure of symptoms and restitution of function in twenty patients. In one child the positive Trendelenburg persisted for three months after all other signs and symptoms had disappeared. In the remaining case a mild recurrence in the form of referred knee pain developed with the onset of influenza five months after all original symptoms had disappeared. These secondary symptoms likewise vanished several days after weight bearing had been resumed in the convalescence. This particular case was instructive also in other respects and is considered in detail in the discussion which follows.

COMMENT

The disease under discussion has been designated as transitory synovitis rather than the broader term arthritis since the lesion seems to be confined to the synovial membrane. Many of the cases were undoubtedly seen in the acute stage, but in neglected cases the disease was more probably in the subacute or chronic stage. The histologic examination in one case was confirmatory. Although the symptoms may be protracted in some cases they may still be considered as "transitory," since resolution is ultimately complete.

The symptoms of transitory synovitis of the hip joint in children may be simulated closely by the early stage of other forms of hip joint disease. This is to be expected, since the synovial pathologic condition may represent the initial lesion in several types of coxitis. The local resistance and immunity of the synovial tissue may determine whether the infection subsides or progresses into a definite form of arthritis. In other words, in transitory synovitis of the hip joint the synovitis constitutes the entire disease but in other hip joint lesions the synovitis may merely represent the point of departure into any one of several disorders of the hip.

The greatest difficulty in diagnosis lies in those borderline cases which closely resemble an early tuberculosis of the hip joint. The physician is confronted with choosing between the needless embarrassment of joint motion by prolonged immobilization in a case of simple synovitis or the graver danger of aggravating tuberculous hip disease by physical therapy and motion after inadequate immobilization. A valuable diagnostic procedure lies in aspiration of the hip joint and inoculation of a guinea-pig with the joint fluid to establish or rule out tuberculosis. Low grade purulent arthritis may be discovered by a cell smear and culture of the cloudy fluid. An excellent point is made by Butler, who advises that these borderline cases should be regarded as "observation hips." By this regimen cases which formerly would have been accepted as definitely tuberculous are now put under observation until the trend of the disease becomes definitive.

REPORT OF CASE

The following case history is presented because it illustrates clearly the difficulty of diagnosis in borderline cases.

History—L. V., a white girl, aged 4 years, was first seen June 6, 1934. We learned that she had fallen from her tricycle eighteen months previously and had experienced intermittent pain in the left knee. Lately she had been improving when moderate pain developed in the left hip associated with a limp.

Physical Examination—This was essentially negative except for pain. There was an adduction (15 degrees), internal rotation (10 degrees) contracture.

Laboratory Examination—The temperature was 99.2 F. The white blood count was 9,200. The tuberculin test was negative.

Röntgen examination did not reveal any pathologic condition.

Treatment—Immobilization in a hip spica was done for eight weeks.

Course—When the cast was removed (August 10) the patient resisted all attempts to move the left hip but had a good range of painless active motion. The repeated tuberculin (Mantoux) test was now strongly positive to both human and bovine strains. Therefore another spica was applied. Two months later (October 11) the cast was removed and motion found to be good. Roentgenograms, however, showed an increase in loss of calcium density in the head of the femur and roof of the acetabulum. A slight roughening appeared in the articular surface of the head of the femur. These facts, plus the knowledge that the patient's mother had died of tuberculosis strongly suggested tuberculosis, so a biopsy was indicated to establish the diagnosis.

Operation—The left hip joint was exposed at operation October 15 through a Sprengel incision. The capsular synovium was hypertrophied and a thin pannus crept over the joint surface at the margins of the head. The femoral and acetabular cartilage were normal in appearance. The bone of the acetabulum was entered subchondrally above the margins of the cartilaginous roof. Curettements of the bone, which was hard, could be removed thus without injury to the underlying cartilage. After closure of the wound, a hip spica was applied.

Pathologic Examination—No signs of tuberculosis were noted in the specimens. The synovial tissue attached to the joint capsule showed only nonspecific inflammatory changes, which were also present to a lesser degree in the fibrous capsule. The bone of the acetabulum was normal except for moderate osteoporosis unassociated with inflammatory changes. The joint cartilage from the margins of the acetabulum showed some early degenerative changes in the middle noncalcified layers. No signs of specific inflammation could be found. The diagnosis was chronic synovitis of the hip joint with collateral osteoporosis.

Postoperative Course—The spica was removed after one month (November 15) and physical therapy was instituted. After four weeks there was complete, painless, unrestricted motion of the hip joint, one-fourth inch of atrophy of the thigh persisted.

Recurrence—The patient had an attack of influenza in May 1935, five months after being considered cured. The pain was referred to the knee, similar to the onset of the primary symptoms. However, by the time walking was resumed during the convalescence, she was symptom free. The hip, when examined one year later, was entirely normal.

SUMMARY

1 Transitory synovitis of the hip joint is essentially a disease of children under 8 years of age. Twenty-two cases are reported.

2 The chief symptoms are limp, pain and muscle spasm. The temperature and white blood count may be elevated moderately. The tuberculin skin reaction and roentgen examination are usually negative.

3 The disease must be differentiated from the early stages of other forms of coxitis, especially tuberculosis. Aspiration of the hip joint and examination of the fluid are suggested as an aid in diagnosis.

4 The treatment is conservative: bed rest, traction or immobilization is advised in the early stages, and physical therapy subsequently. The prognosis for functional recovery is excellent.

THE CONTROL OF MENINGOCOCCIC MENINGITIS EPIDEMICS

BY ACTIVE IMMUNIZATION WITH MENINGOCOCCUS
SOLUBLE TOXIN: A PRELIMINARY REPORT

DWIGHT M. KUHNS, MD

Captain, Medical Corps, United States Army, Seventh Corps
Area Research Board

FORT LEAVENWORTH, KAN.

An epidemic of meningococcic meningitis is to be discussed in which all the present standard methods for prevention and control were given as thorough a trial as will usually be possible. A difficult problem presented itself in that cases continued to occur in spite of the application of these control measures.

Active immunization against the meningococcus, which heretofore had not been used in the presence of an epidemic, was then considered as a possible means of control, and a study of a meningococcus broth culture was begun to find a product for that purpose. The filtrate of the broth culture containing a soluble toxin¹ was selected as a skin testing and immunizing substance and was given a trial to determine its value as a means of control in the epidemic. It is recognized that to determine its value as a protective agent it will have to be used in numerous outbreaks.

SITUATION, CASE LOCATION, SEQUENCE AND MORTALITY OF THE EPIDEMIC

In the spring of 1935 an epidemic of meningococcic meningitis occurred in Atchinson County, Mo. There were seventeen cases, nine of these occurred in a CCC camp located in the environs of Tarkio, four in the adjacent town of Tarkio itself, three in Fairfax, a small village 8 miles distant, and one on a nearby farm.

The sequence is shown in chart 1. The first case occurred in Tarkio, in a middle aged housewife. Three months later the second, third and fourth cases occurred

From the Station Hospital and the Seventh Corps Area Laboratory. Read before the Spring Medico-Military Symposium arranged by the Kansas City Southwest Clinical Society and the Medical Department, Seventh Corps Area, United States Army, Kansas City, Mo., March 10, 1936.

¹ Ferry, N. S.; Norton, J. F. and Steele, A. H. Studies of the Properties of Bouillon Filtrates of Meningococcus. Production of Soluble Toxin. J. Immunol. 21: 293-312 (Oct.) 1931.

in the CCC camp Following this, as can be seen on the spot map, the sequence was not continuous in any one place

We were apparently dealing with a virulent strain or strains of the meningococcus There was a mortality of 83⅓ per cent in six untreated cases outside the CCC camp

CASE INTERVAL AND SOURCE OF INFECTION

The epidemic was slow in pace as is frequently the case In the beginning in the camp, the first three cases occurred at intervals of seventeen days (chart 2), then,

as might be expected, the interval was shortened and later the interval was increased again

The source of infection in Camp Crystal² was highly problematic As indicated in chart 2, patient 1 may have received his infection from a carrier Patient 2 was an acting male nurse in the camp infirmary and nursed patient 1 a few hours before the case was diagnosed, and he was sent to Station Hospital, Fort Leavenworth Patient 2, before symptoms of meningitis developed and before he was sent to the station

Chart 1—Case location sequence and mortality in meningococcal meningitis epidemic The white circles indicate cases in which recovery occurred and the black circles the fatal cases

hospital, nursed patients 3, 5 and 6, who were convalescing from the mumps Of the remaining cases no close contact could be established Although the foregoing is mentioned as a possible chain of transmission, these patients could very well have been individuals carrying meningococci in the nasopharynx, whose immunity became lowered to such an extent that they became infected with their own organism and developed a meningococcemia and meningitis This could account for the long incubation periods that are noted on the chart

Other factors that may have influenced the spread of meningitis in the camp were

1 Weather conditions The epidemic occurred in the spring of the year during an unusually long cold rainy season

2 Crowding This seemed to be a most important predisposing factor The greatest number of cases occurred in Camp Crystal, where there was the greatest density of population

3 Lowered immunity There was a lowered immunity, as manifested by a high incidence of colds, influenza, nasopharyngitis, middle ear infections and mumps The general physical condition of the men appeared to be good, most of them were seasoned enrollees with from five to six months' service

CONTROL MEASURES

The usual measures for the control of meningococcal meningitis were instituted and were as follows

1 Early diagnosis and isolation of known cases The camp surgeon was alert and diagnosed his cases early, and the patients were immediately transferred to the isolation ward at the Station Hospital, Fort Leavenworth, Kansas

2 Quarantine The entire camp was placed under a working quarantine for fourteen days following each case

3 Daily medical examination Examinations were conducted daily to isolate promptly early cases of meningitis

4 Bacteriologic examination Bacteriologic examination for carriers and isolation of positive carriers were done

5 Sanitation A general clean-up program was instituted and maintained throughout the epidemic

6 Personal hygiene Detailed instructions were given to the men relative to this subject

7 Prevention of the spread of the infection through eating utensils, food handlers, and food Sterilization of eating utensils, culturing of food handlers and inspection of food were carried out

8 Crowding There was a reduction in crowding, fatigue and exposure

9 Proper ventilation and bed spacing Three feet between cots was required and head to foot sleeping was initiated

Before the epidemic was over it was expedient to divide the camp into four side camps of approximately fifty men each This, as can readily be seen, aided greatly in reducing close contact

RESULTS OF BACTERIOLOGIC CULTURAL STUDY AT CAMP CRYSTAL

Because by some a great deal of confidence is placed in the control of epidemics by taking cultures of and isolating the carriers, a cultural study at Camp Crystal was undertaken to attempt to determine the value of this procedure

Chart 2—Case interval and source of infection Patient 2 a male nurse nursed patient 1 the first case in the camp The third fifth and sixth patients to contract epidemic meningitis had mumps and were attended by patient 2 while he was in the prodromal stage of epidemic meningitis

The plan of procedure was to take a culture of all the 250 enrollees, both positive and negative, on four successive weeks, also to take a culture of the members of another, nonepidemic camp, 20 miles distant, as a control, to determine whether the carrier rate was higher in the epidemic camp than in the nonepidemic camp Table 1 presents the results of this study

The greatest number of enrollees in the epidemic camp to yield positive cultures from the nasopharynx

² The CCC camp Company 1742 Tarkio Mo will be referred to as Camp Crystal

at one time was eleven, or 4.4 per cent, and in the control camp seven, or 3.5 per cent. The greatest number showing typical colonies at one time, only on blood plates, was twenty-five in the epidemic camp and seventeen in the control camp. The difference is hardly significant.

A study of the records also showed that there were four types of carriers: (1) early cases, (2) temporary carriers, (3) intermittent carriers and (4) chronic carriers. These different types of carriers demonstrate the futility of taking cultures of and isolating all indi-

viduals who were carriers of meningococci. In order to find all the carriers in a camp it would be necessary to take cultures of the entire surface of the upper respiratory tract of each individual in the group at frequent intervals during the day over a long period of time.

Of the control measures used in the epidemic, the one considered to be of the greatest value was separating individuals the greatest distance possible from one another. Although this is desirable, it is not always possible to do this effectively.

All the other control measures used are important and, unless they have been enforced, not all has been done that can be done in controlling the disease. However, the fact remains that although all the present methods of control available were carried out, cases did continue to occur in this epidemic.

CONSIDERATION OF SKIN TESTING AND ACTIVE IMMUNIZATION AS A MEANS OF CONTROL

The greatest success in controlling infectious diseases in the past has been through the medium of artificial immunization. Ferry and Steele³ in the spring of 1935 described the use of a meningococcus soluble toxin for skin testing and active immunization of 2,000 orphan children in Detroit. Two hundred and thirty-two children were immunized with meningococcus filtrate, eight weeks following immunization, 66.8 per cent were found to have negative skin test reactions.

If positive skin test reactions became negative after subcutaneous inoculation with soluble toxin it was reasonable to infer that the same procedure might possibly protect them from developing the disease. No conclusive clinical data were available as to the protective value of active immunization with this toxin in the presence of an epidemic or the impending danger of an epidemic, nor were there data as to what the skin test would show on individuals as they were coming down with the disease or after they had recently recovered.

³ Ferry, N. S. and Steele, A. H. Active Immunization with Meningococcus Toxin. *J. A. M. A.* 104: 983-984 (March 23) 1935.

TESTS CARRIED OUT TO DETERMINE THE MOST SUITABLE PRODUCT FOR SKIN TESTING⁴

Our method of producing a skin testing substance was similar to that of Ferry,³ which was simply to grow the meningococci in a hormone veal infusion broth medium⁵ in 1,000 cc Florence flasks. After cultivation for four days, the culture was killed by the addition of sufficient merthiolate to make a final concentration of 1:10,000 and was then passed through a Pasteur-Chamberland filter with a porosity of L₇. The most difficult phase of the production of the toxin was the technique of making cultures of recently isolated strains and the training of these strains to produce pellicles,⁶ which appear to be necessary for toxin production. The inoculation of large flasks to produce heavy simultaneous growths and the mediums used for carrying the cultures will be described at a later date.

For the purpose of studying the separable fractions of the broth culture, it was divided into the following five parts, and skin tests with each portion were made on the same individual.

1. Merthiolated broth culture. The whole culture was killed and used as a skin testing substance. In this instance the various fractions that were used for comparison were obtained from the same broth culture that contained 2,000 million cocci per cubic centimeter.

2. Exotoxin. The filtrate from the meningococcus broth culture. This fraction hereafter will be referred to as exotoxin for the purpose of identification. There are two reasons why we believe that this is an exotoxin: (a) The filtrate of the autolyzed meningococci with distilled water grown on solid mediums did not produce positive skin reactions and (b) in broth mediums meningococci were found to grow mainly on the surface in the form of a pellicle and up to the time of filtering.

Edema as well as erythema was noted in reading tests of fractions named. All skin tests were made with a dilution of 1:100. All tests were made intracutaneously with 0.05 cc of test solution.

showed no detectable precipitation of the pellicle, and no ruptured forms of meningococci on microscopic examination.

3. Filtrate containing exotoxin and endotoxin. The culture was incubated twenty-four hours after it was killed with merthiolate to produce complete autolysis of the meningococci and then filtered. This filtrate was added to an equal part of 2, thus giving a solution containing both an exotoxin and an endotoxin.

⁴ These tests were carried out with the assistance of Miss Pea I. Moorman.

4 Heated filtrate The filtrate was heated to 120 C at 15 pounds pressure for one hour. Boiling for one hour did not make the toxin inactive. Ferry has reported recently that autoclaving for thirty minutes will destroy the toxin in some filtrates.

5 Endotoxin This was made from the meningococci that remained after the culture was filtered through the Pasteur-Chamberland filter. These meningococci were autolyzed by adding distilled water and incubating for twenty-four hours¹ and diluting to the original quantity of the broth culture with saline solution.

Tables 2, 3, 4 and 5 show a comparison of the intracutaneous reactions of the five named fractions.

Column 1 Skin reactions from the whole culture were the greatest. Further studies should be made of the whole culture to determine its value as a skin testing substance. The additional reaction is thought to be due to the membranes of the meningococci themselves. A further study of this fraction is being made.

Column 2 This is the product or filtrate of the meningococcus broth culture to be given a trial in skin testing and active immunization for and against meningococcal meningitis.

Column 3 The fraction containing the exotoxin and the endotoxin produced approximately the same skin reactions as the exotoxin. This would suggest that the endotoxin present in this fraction was inactive as far as skin reactions were concerned.

Column 4 The fraction containing the heated filtrate showed on skin testing that the exotoxin was rendered

inactive by the amount of heat it had received and indicates that the reaction caused by the exotoxin is caused by a substance which can be destroyed by heat. This serves also as a control for the reaction of the whole culture and the exotoxin.

Column 5 The fifth fraction containing the endotoxin is shown by the tables to be inert as a substance

producing skin reactions. We also produced an autolysis of meningococcus grown on solid mediums in distilled water and found the exotoxin, when prepared in this manner, to be inert. Meningococci were also grown on solid mediums, washed with hormone broth and filtered, and the filtrate was used as a skin testing substance. It produced no reactions on ten individuals sensitive to the filtrate. This experiment was made to determine whether meningococci when grown on solid mediums would produce a toxin on their surfaces.

The results showed (1) that meningococcus exotoxin produces positive reactions on sensitive individuals, (2) that autolyzed meningococcus filtrate does not produce positive skin reactions on the same individuals, and (3) that the heated exotoxin does not produce positive skin reactions on the same individuals. The foregoing results are in confirmation of the experiment done by Ferry, Norton and Steele¹ in 1931, when the first study of a meningococcus soluble toxin was made.

Table 6 illustrates the average skin reactions to the five fractions in the order named.

DETERMINATION OF THE SKIN TEST UNIT DOSE

In addition to using sensitive individuals to determine the skin test unit dose, similar to the manner of Ferry,³ it was conceived that the skin test unit dose should be the amount of exotoxin that will give a positive reaction in an individual who is susceptible to the disease (as proved by his developing meningitis) and not the amount to which the individual is sensitive (and who does not develop the disease).³ In using this conception there can be no question as to the susceptibility of the individual who develops the disease. A skin test on this individual, when the first symptoms are noted, should be the skin test unit of the susceptible. Accordingly, a patient developing the disease on the first day of symptoms was given skin tests in dilutions varying from 1:100,000 to 1:10. Only one case has been available for skin testing to determine the level of immunity reached before and after immunization. In the instance of Bales (table 7), when he came down with the disease he reacted to dilutions of 1:1,000. After recovery and following treatment with antimeningococcus serum he reacted only to 1:10, thus showing that a positive skin test with a dilution of 1:100 before

his illness would have indicated his susceptibility and would have been the proper skin test dose in this case. To determine more accurately the skin test dose to which the average susceptible individual will react and the average amount of immunizing substance necessary

to produce the level of immunity desired these skin test titrations should be done in a large series of cases in which the disease is actually developing.

Since beginning this work we have made skin tests of all patients with meningococcal meningitis four and six weeks after they recovered from the disease (table 8). Table 8 indicates that immunity to meningococcus exotoxin is present after recovery from the disease and that the exotoxin skin test may reflect the amount of immunity possessed by an individual.

For the purpose of obtaining further data as to what dilution of our toxin would produce a positive reaction on the average sensitive individual skin tests of twenty recruits for the army were made. The results are shown in table 9.

At this time we were unable to titrate the toxicity of our toxin by the use of animals. Of the animals used—rabbits, guinea-pigs and mice—only rabbits could be killed occasionally. We hope to give mice a further trial by active immunization with toxin for protection against meningococci suspended in mucin given intraperitoneally.⁶

Skin test reactions on individuals sensitive to the exotoxin were used to determine the toxicity of each new lot of exotoxin produced. In the future this dose may be controlled in a degree by testing individuals developing the disease.

Dilution of 1:100 of filtrate used for skin testing

SKIN TESTING AND IMMUNIZATION AT CAMP CRYSTAL⁹

After all the control measures available were used, meningitis cases, as stated before, continued to occur at Camp Crystal, the last one being July 25, 1935. In addition to the continuation of control measures, it was

decided to make skin tests and to immunize all the enrollees at Camp Crystal with meningococcus exotoxin, August 8. Passive immunization by the use of antimeningococcus serum was considered but was not deemed practical in this situation.

Recently cultured meningococcus epidemic strain type 3 and stock strains from the National Institute of Health types 1 and 3 were used in producing the exotoxin for skin testing and immunizing the members of the camp. Equal parts of the filtrate from the three strains were used. The epidemic strain, type 3, was found to be a very virulent strain. The skin test unit dose of this exotoxin was 0.05 cc of 1:1,000 dilution of the filtrate. That is, it produced an edema and erythema 1 cm in diameter in sensitive individuals, seven out of twenty, as shown in table 9.

Recently 2,000 CCC enrollees, enrolled directly from urban and rural civilian life, were skin tested with 1:1,000 dilution of filtrate made in April 1936, and in this group 37 per cent were found to have a one plus or greater skin test reaction.

TABLE 10—Results of Skin Tests at Camp Crystal Before and After Subcutaneous Inoculation with Full Strength Meningococcus Filtrate Types 1 and 3

| | |
|--|-----------|
| 1. Total number of men tested | 187 |
| 2. Total number men positive one plus or greater | 14 (7.4%) |
| 3. Total number men immunized with 0.1 cc, 0.2 cc, 0.3 cc, and 0.4 cc full strength filtrate at weekly intervals | 163 |
| 4. Results of skin tests three weeks following immunization | |
| a. Number skin tested | 64 |
| b. Number positive one plus + | 0 |
| c. Number positive plus minus + - | 5 |
| d. Number negative | 59 |

Table 10 gives the results of skin tests before and after immunization with full strength filtrate. This was given at weekly intervals, and after it was completed each individual had received a total of 1.3 cc of full strength filtrate, which, by use of the titration already stated, contained 26,000 skin test units.

Because of the rapid change in personnel in the camp, only ninety-four of the original 187 men were available for testing following immunization. The percentage positive of the ninety-four before immunization was 5.3 and following immunization 0. We were unable to take skin tests of these men at a later date to determine whether additional immunity had developed. There were only slight local reactions to the small immunization doses that were given. For this reason it is possible that larger doses of the filtrate could be tolerated. Experiments are being conducted at the present time to determine how large an immunizing dose of the full strength filtrate can be tolerated. Controls containing the same concentration of merthiolate and broth were used with all skin tests, and in all cases the results were negative. All new enrollees admitted to the camp following this were immunized on admission. No further cases of meningitis developed in the camp following immunization.

7. Branham Sarah, National Institute of Health, personal communication to the author. Rake, Geoffrey. Studies on Meningococcus Infections. J. Exper. Med. 67: 549-559 (April) 1933.

8. Miller, C. P. Experimental Meningococcal Infection in Mice. Science 78: 340 (Oct. 13) 1933.

9. This was done with the cooperation of Dr. Charles Fogarty.

The change in the confidence of the enrollees and all the civil groups was quite noticeable, so much so that the health officer and school board of Tarkio requested that the children of the high school and grade school be given the same advantages as the enrollees in the camp. With the cooperation of the Missouri State Board of Health, the camp surgeon carried out skin testing and immunization in the high school and grade school. The same exotoxin was used as for the Camp

immunized, and, although four additional cases have occurred during that time, not one has occurred among those who were immunized.

AN EXAMPLE OF HOW SKIN TESTING AND
IMMUNIZATION WITH MENINGOCOCCUS
EXOTOXIN MAY BE USED FOR THE
CONTROL OF A MENINGITIS
EPIDEMIC¹⁰

The ideal situation in which to use active immunization is not after the epidemic has progressed but obviously at the onset of the epidemic. Such a situation presented itself at Burlington, Kan., in Camp Coffey, a CCC camp. There again known control measures were used after the first case occurred but did not prevent a second case from occurring in twelve days. On the development of the second case, skin testing and immunization of the camp with our toxin were begun.

At the same time a culture study of the camp was made for carriers by Ross Laybourn, Kansas state bacteriologist, the results of which are included in table 13.

For skin testing and immunization, meningococcus exotoxin types 1 and 3, from one of the recently isolated Tarkio strains, and from stock strains from the National Institute of Health, were used. The skin test dose in this instance was 0.05 cc of 1:100 dilution of the filtrate. Table 14 gives the results of the skin tests before and after immunization. To prevent a reaction

| Number positive skin reactions one plus or greater | 23 | 23% |

Skin tests made May 18, 1936, 0.05 cc of a dilution 1:100 of full strength filtrate from a whole broth culture containing 2,000 million cocci per cubic centimeter was used.

Crystal group, but, since it had decreased in toxicity³ in the two months intervening, a dilution of 1:300 was equivalent to 1:1,000 by skin tests on controls.

Since the first batch of filtrate was made, ten new filtrates have been made and have been found to hold their potency remarkably well, 0.05 cc of a dilution of 1:100 of the filtrate has been found to produce constantly a reaction 1 cm or greater in sensitive individuals. A meningococcus filtrate made nine months ago shows 10 per cent less skin reaction when the old and the new filtrates were compared by skin testing on the same 840 enrollees (table 11). The filtrate is now being made from equal parts of types 1, 2, 3 and 4 stock strains from the National Institute of Health and types 1, 2 and 3 from epidemic strains in this area.

* Immunizing dose for high school children full strength filtrate 0.1 cc, 0.3 cc, 0.4 cc, at weekly intervals given subcutaneously 1:300 dilution of filtrate used 4,800 skin test units of toxin used. Grade school children full strength filtrate 0.1 cc, 0.2 cc, 0.25 cc at weekly intervals given subcutaneously 1:300 dilution of filtrate used for skin test log.

The results on the school children are included because of the value of the data obtained by using two different age groups (table 12). The last skin test was made one week after the last immunizing dose. A further investigation is being made to see how much and how soon immunity develops. In the school children it was noted that the children in a family that had recently moved to the community showed greater sensitivity on skin testing than the others. Seven months has elapsed since the children in this community were

| Total number temporary carriers | 5 |

due to trauma rather than to the toxin, 0.05 cc of skin testing solution was used. Up to the present time no skin reactions have been obtained from using the mercuriolated broth or the heated filtrate.

In table 14 a study of the results from skin testing at Camp Coffey before immunization show that 43 per cent of the enrollees gave a one plus or greater skin reaction. Seventy-two of this 43 per cent were immunized with the filtrate and 20 per cent gave positive skin tests six weeks after immunization was initiated. Four months following immunization, forty-one were available for skin testing, and of these only 2 per cent were positive, which indicated that there was a definite trend from positive to negative.

In selecting the enrollees for immunization, only those showing one plus or greater skin reaction were immunized. In order to prevent severe reactions when immunizing, the skin test may be used as a protective measure. If the individual on skin testing exhibits a skin reaction greater than 3 cm in diameter this fact should be considered as a danger signal and the size of the immunizing dose should be adjusted in direct proportion to the skin reaction. By using this criterion, immunization can be carried out without danger of severe reactions to the toxin. Six of the seven enrollees found on culture to be carriers had a one plus skin test. There were no severe initial cutaneous reactions in this series in which the following doses were used at intervals of four days (table 11). A four day interval was used because it had been found that

¹⁰ This experiment was carried out with the assistance of Dr. Timothy P. Flynn.

the local reaction usually disappeared in from two to three days and because of the fact that the more rapid the immunization the more valuable the procedure in the presence of a possible epidemic

The decrease in local reaction to the substance suggests that the enrollees in this instance developed immunity very rapidly. Up to the present time no further cases of epidemic meningitis have occurred in the camp or in the outside community

0.05 cc of methionated broth was used as a control on the skin tests and were negative

SUMMARY

1 An epidemic of meningococcal meningitis occurred in which there were seventeen cases

(a) The greatest number of cases occurred where there was the greatest density of population, in a CCC camp near a small town

(b) The mortality in the epidemic was 83 per cent in six untreated cases outside the CCC camp and 11 per cent in nine cases treated early with antimeningococcus serum

2 A culture for carriers was made in the CCC camp, Camp Crystal, on four successive weeks and the highest number found positive at one time was 4.4 per cent. A culture was made at the same time on a nonepidemic camp 20 miles distant and 3.5 per cent were positive

On another cultural study made by Ross Laybourn at Camp Coffey, 3.5 per cent were found positive

3 It was noted that cases continued to occur in the CCC camps after all the control measures available at the present time were enforced. The control measure considered to be of the greatest value was the separation of individuals the greatest distance possible from one another

4 A study of filter separable fractions of meningococcus broth culture was made to determine the skin reactive properties of Gordon's four types of meningococcus

(a) It was found that the whole culture produced the greatest reaction and the filtrate produced the next greatest reaction

(b) The heated filtrate produced no reaction and served as a control

(c) The filtrate from autolyzed meningococci, or endotoxin, produced no skin reaction

5 The filtrate was given a trial in an epidemic of meningitis to determine its value as a skin testing and immunizing substance

6 A new approach as to how to determine the level of immunity of a susceptible individual by skin testing with graduated dilutions of filtrate on an individual coming down with the disease and again after recovery is suggested as a possible method of determining the skin test unit dose

(a) The amount of filtrate necessary to change the skin test from positive to negative, in dilutions shown in table 7, should be the amount necessary to immunize the individual

(b) The skin test reaction could be a very valuable guide in the treatment of the individual

7 The filtrate was used in a dilution of 1:100 as a skin testing substance on two and four week convalescents and gave consistently negative tests

8 Skin testing on sensitive and susceptible individuals is the only available means at the present time of determining the toxicity of the exotoxin. Although the laboratory animals do react, the effects are not sufficiently consistent to titrate the potency of the product

9 A 1:100 dilution of a filtrate produced from types 1, 2, 3 and 4 meningococcus was used to make skin tests of 2,000 newly enrolled CCC members, 37 per cent gave a skin reaction of one plus or greater

10 Although the filtrate that was used in the Tarkio epidemic did not appear as stable as the one we are developing at the present time, the skin test there indicates a trend from positive to negative

11 A filtrate aged 9 months in a refrigerator held at 50°C reacts on 10 per cent less of the same enrollees than one made nine months later

12 An opportunity to observe the change in skin tests after subcutaneous inoculation with full strength filtrate, after an interval of four months was offered at Camp Coffey and the trend was definitely from positive to negative

13 Among 395 individuals receiving meningococcus filtrate subcutaneously, none have developed meningitis even though in the Tarkio epidemic four cases devel-

TABLE 15—Reactions from Active Immunization with Exotoxin

| Dose | Amount Full Strength Filtrate | Reactions |
|--------|-------------------------------|--|
| First | 0.2 cc | All 86 men had sore arms. 21 had mild systemic reactions (the presence of these was difficult to determine owing to the high percentage of upper respiratory diseases). 1 had a moderately severe reaction (headache, backache, malaise, clear discharge from nose). |
| Second | 0.5 cc | 23 had local reactions. 18 had mild systemic. 0 had moderately severe. 2 had urticaria, mild, local near site of injection (no increase on third dose for moderately severe or urticaria reactors). |
| Third | 1.0 cc | Local and mild systemic reactions similar to 2d dose. No severe reactors. |
| Fourth | 1.5 cc | Only one moderately severe reactor. |

oped among those not immunized. Ten months has intervened since this immunization was first initiated

(a) The filtrate has been used in three outbreaks not reported in this paper with the same results as described

14 It is to be remembered that this is only a preliminary report and in order to prove the value of the meningococcus filtrate as a skin testing and immunizing agent it should be used in a large number of beginning epidemics and over a long period of time

Station Hospital

TRICHOMONAS VAGINALIS INFESTATION IN THE MALE

PAUL H. NITSCHKE, M.D.
PORTLAND, ORE

Since Donne's¹ description of the parasite *Trichomonas vaginalis* in 1836, the reports of numerous observers have emphasized its very frequent occurrence in women, in fact, a clinical entity known as trichomonas vaginitis is known to every physician. Furthermore, *Trichomonas vaginalis* was reported as a cause of infection in the renal pelvis by Lewis and Carroll² and later by Ayer and Neil³.

Cystoscopic bladder manifestations in women suffering with trichomonas infestation have been observed by Visser⁴ and others. I myself have observed two instances. During cystoscopy in an unmarried woman, aged 22, it was noted that the bladder neck, trigon and lower half of the bladder were diffusely reddened. Though *Trichomonas vaginalis* was found in the urine and vaginal secretion, the presence of a rather severe interstitial cystitis (Hunner's ulcer) precluded any accurate elucidation of clinical symptoms. In the second patient, a married woman, aged 22, previous cystoscopy for ureteral stricture revealed a normal bladder. A second cystoscopy some three weeks later revealed an intense bright redness of the entire bladder mucosa. Individual vessel markings were lost. The right and left ureteral orifices, other than being included in the generalized redness, were normal. No edema was present. Right and left ureteral catheter specimens were clear and showed microscopically only an occasional red blood cell. Cultures of ureteral specimens showed no growth. The bladder urine was clear and was acid in reaction, and tests for both albumin and sugar were negative. Microscopic examination of the uncentrifuged specimen revealed an occasional epithelial, pus and red blood cell, and motile trichomonads. *Trichomonas vaginalis* was of course present in the vaginal secretion. Careful questioning of the patient failed to reveal any symptoms referable to the urinary tract. Cystoscopy two weeks later revealed a normal bladder. *Trichomonas vaginalis* was absent in the urine but present in the vaginal secretion. Urinary symptoms such as dysuria, nocturia, or both, with some burning on urination may have been present, however.

The discovery by Miura⁵ in 1893 of *Trichomonas vaginalis* in the voided urine of a man aged 52 revealed its occurrence in the male. Miura's patient did not complain of urinary symptoms. Marchand⁶ reported an instance of *Trichomonas* in the male in 1894, and Dock⁷ also reported its occurrence before the turn of the century. Since then, rather sporadic reports have found their way into the literature. In 1924 Katsunuma⁸ reported *Trichomonas vaginalis* in the urine of a 3 year old boy, the source of the parasite was later found in the preputial sac, where it caused a redness and edema.

Čapek⁹ in 1927 first reported trichomonas urethritis in the male but also observed microscopic and macroscopic blood in the urine. Grimm's masterly description in his report of five cases of trichomonas urethritis leaves little to the imagination.

Riba and Perry¹⁰ reported two instances of trichomonas infestation of the prostate in 1929, antedating May¹¹ by almost two years. May did, however, prove through cystoscopy that the bladder need not be involved in trichomonas infestation of the prostate.

The only instance in which involvement of the upper urinary tract might be suspected in the male was reported by Rosenthal¹² in 1930. A widower, aged 72, developed symptoms of infection of the urinary tract five weeks after an operation for removal of gallstones. *Trichomonas vaginalis* was found in the urine and in one instance a renal cast containing a flagellate form was seen. Rosenthal, however, attributes the symptoms to the presence of *Bacillus coli-communis*.

Concerning the frequency of *Trichomonas vaginalis* in men, accurate statistics are not available. Indeed, the literature reveals a number of opinions of wide variation, which, however, on closer scrutiny merely enlarge our knowledge concerning *Trichomonas vaginalis* in the male.

On the one hand, 32,000 examinations of prostatic secretion in the Mayo Clinic¹³ revealed the presence of *Trichomonas vaginalis* sixteen times. Pelouze¹⁴ reported eight instances of prostatic infestation in four years. Lately Allen¹⁵ has reported six instances of prostatic infestation found by examining the husbands of patients having trichomonas vaginitis. On the other hand, Grimm¹⁶ was able to demonstrate *Trichomonas vaginalis* five times in a series of twenty-five cases of nonspecific urethritis. In our own series we were able to demonstrate *Trichomonas vaginalis* five times in forty instances of so-called nonspecific urethritis.

Finally Drummond¹⁷ reported four instances of prostatic infestation with *Trichomonas vaginalis* found by examining the prostatic secretion of five men whose wives were suffering from trichomonas vaginitis. Drummond reached the conclusion that "the male infested with *Trichomonas* usually presents no symptoms or physical sign" and that "it has been confused with other nonspecific discharges of the male urethra."

During the past eighteen months we have observed the occurrence of *Trichomonas vaginalis* in the male five times in forty instances of so-called nonspecific urethritis. The process was one of elimination.

CASE 1—A man, aged 23, had been married one year when he was seen, Dec. 27, 1934. He had had gonorrhea two and one-half years before. He had had no extramarital relations. He complained of a slight watery discharge, which had been present intermittently for six months. There were no other complaints. The family physician had been treating the patient for gonorrhea.

Examination revealed a very slight grayish watery discharge present at the meatus. Gram's stain of a smear showed only

a few gram positive cocci and a few pus cells. Under ordinary urethral irrigations and prostatic massage, the urethral discharge disappeared. Though *Trichomonas* was suspected it was not found, either in the urine or in the prostatic secretion.

The urethral discharge reappeared in February 1935, and the manifestations were the same as those just described. The patient was told to have his wife examined by a gynecologist for trichomonas vaginitis, but this he refused to have done. After a few weeks of routine treatment the discharge again disappeared.

In June 1935 the discharge again reappeared and *Trichomonas vaginalis* was found in the prostatic secretion and an occasional parasite was present in the urine. A few days later the wife was examined by a gynecologist and *Trichomonas vaginalis* was found to be present in the vaginal secretion in large numbers.

CASE 2—A married man aged 34 was referred by a gynecologist June 13 1935 because he had a urethral discharge and his wife was suffering from trichomonas vaginitis. The history, except that the patient had had gonorrhea in 1931 with no complications was negative. The patient admitted extramarital exposure eighteen days before. The patient's only complaint was the presence of a slight urethral discharge for the last two days.

Examination revealed a scant grayish watery urethral discharge when the urethra was stripped. Stained smears were negative for gonococci and only a few pus cells were seen. Irrigation of the anterior urethra was done with warm physiologic solution of sodium chloride in a small bulb syringe and immediate examination of the contents as a warm wet specimen was negative for *Trichomonas*. Both glasses of urine were clear, but there were some large shreds in the first glass. The urine was acid. The tests for albumin and sugar were negative and microscopically a few pus cells were seen but no trichomonads were present. The patient was placed on irrigations.

June 17 rectal digital palpation revealed a slightly enlarged prostate the right upper pole of which was firmer than normal. The seminal vesicles were not palpable. Immediate examination of a wet specimen of prostatic secretion mixed with physiologic solution of sodium chloride revealed numerous pus cells and some few motile trichomonads. Gram's stain showed some gram-positive cocci and numerous pus cells. The prostate was again massaged five days later and the patient was not seen again for some time.

July 10 the patient had an attack of acute prostatitis with frequency, dysuria and terminal hematuria for which he was treated palliatively at home.

August 24 the prostatic secretion was again examined and the specimen was negative for *Trichomonas vaginalis*. Further treatment for chronic prostatitis was carried out. Some half dozen prostatic fluid examinations have since been negative for *Trichomonas*.

CASE 3—A man, aged 19, single, seen Nov 30 1935 complained of a urethral discharge, burning in the urethra at the end of urination and frequency. He stated that he had had no venereal disease. The patient admitted a dozen exposures to the same girl, the last exposure having been Sept. 14 1935. The symptoms began about October 1 and consisted of hourly frequency, burning on urination and a yellowish discharge which stained the clothing. Gonorrhea was diagnosed by the first physician consulted but no treatment was given. The patient later came to Portland for further examination.

Examination showed a small amount of thin watery discharge at the external meatus. Gram's stain of a smear showed a number of gram-positive cocci and short gram-negative bacilli. Numerous pus cells were present. As there was not enough discharge for examination of a wet specimen the anterior urethra was irrigated as previously described and some active trichomonads could be made out. Both glasses of urine were cloudy and acid in reaction and tests revealed the presence of some albumin but no sugar. Microscopic examination showed numerous pus cells singly and in clumps and a few motile trichomonads. Urine cultures showed *Staphylococcus albus* and *Bacillus coli*. As the condition was somewhat acute the prostate was not examined, but there is no doubt as to its involvement. The patient is still undergoing treatment.

The girl in this instance has been treated for some time and is still being treated for trichomonas vaginitis.

CASE 4—A man aged 26 had been married two and one-half years when seen, Dec 2 1935. The patient has had a urethral discharge off and on for the last two years. He also complains of a slight burning on urination and an occasional dull aching pain situated in the right lower part of the back. The patient was treated by his family doctor in January 1934 and also in the summer of 1935 by weekly prostatic massage. He was told he had a nonspecific urethritis.

Examination revealed a very slight (practically absent) grayish watery discharge at the external meatus. Irrigation of the urethra revealed no trichomonads. The urine was acid, and tests for both albumin and sugar were negative. Microscopically only a few pus cells were seen. A few days later a few trichomonads were seen in the urine, the first glass being used. Rectal examination revealed a small prostate somewhat firmer than normal at the right base. The normal markings were preserved and the seminal vesicles were not felt. After a few examinations *Trichomonas vaginalis* was found in the prostatic fluid.

After the patient was found to harbor *Trichomonas vaginalis*, his wife was sent to a gynecologist, who found a rather severe trichomonas vaginitis, the discharge of which contained many active trichomonads.

CASE 5—A man aged 33 had been married one day when seen Dec 14 1935. He complained only of a slight urethral discharge since exposure to a woman other than his wife. He stated that he was told afterward by the woman that she had a disease but could not "understand the name." This exposure took place in August 1935. The patient also had sex relations with his wife the day before.

The history other than gonorrhea at the age of 16 and again in 1934, was negative. The patient's complaints were limited to the slight discharge.

Examination revealed a very slight grayish watery discharge in the external meatus. There was not enough discharge for a wet specimen so the anterior urethra was irrigated with physiologic solution of sodium chloride as previously described. Examination of this fluid revealed a few motile trichomonads. The urine was acid and the test for albumin showed a faint trace but the test for sugar was negative. Microscopic examination showed an occasional pus cell and an occasional red blood cell. After several examinations *Trichomonas vaginalis* was found in the urine.

Rectal examination revealed a small prostate with no abnormalities. The seminal vesicles were not felt. Two different specimens from the prostate failed to reveal *Trichomonas vaginalis*. The patient left in a few days for his home in Idaho so further examination was impossible.

It was of course impossible to examine the first woman, but the wife was sent to a gynecologist who found that she had a trichomonas vaginitis of some duration. The history might lead one to believe that the first woman had a trichomonas infestation. However, if one disregarded the first instance, assuming that the patient's discharge was due to some other organism it might then be assumed that the trichomonads found in the anterior urethra were due to the first marital exposure of the preceding day and that the changes in the anterior urethra and the first glass of urine and not in the prostatic fluid could be explained on a time basis. I am of the opinion, however, that the parasite was harbored also by the first woman and that further examination would have revealed its presence in the prostate.

I have presented five instances of *Trichomonas vaginalis* infestation in the male. Each patient complained of a slight watery discharge. I do not maintain that *Trichomonas* is the cause of the discharge, for indeed even in this small group there is evidence that the parasite is not a pus producer per se and that the presence of other organisms increases the discharge, as is shown in case 3 and again in case 2, in which the discharge continued, owing to chronic prostatitis, after examination had shown that the parasite had disappeared from the prostate. I do believe, however, that *Trichomonas vaginalis* is present in a fair percentage of the discharges of so-called nonspecific urethritis, and for this reason should be looked for as a routine.

Treatment of *Trichomonas* infestation in the male may be approached from the standpoint of prophylaxis against reinfection of the female. That *Trichomonas vaginalis* may be present in the prostate of the husband and serve as a source of reinfection of the wife is only too apparent. That the male may not be aware of his infectiousness is aptly illustrated by the fact that in the first instance on record, reported by Miura, there were no urinary symptoms. Later Allen's¹⁵ routine observations and the instances disclosed by Drummond¹⁷ are ample evidence of this. In my own cases the discovery of *Trichomonas vaginalis* in males who complained only of a slight urethral discharge, some being intermittent in character and easily overlooked except by the most fastidious, together with the added important factor of finding the parasite in the female in every instance in which it was previously diagnosed in the male is most convincing. Finally, the examination of the lower part of the urinary tract in women should be remembered, even though symptoms are absent when one is treating *Trichomonas vaginalis* in the female.

Therapy in the male depends on two factors, the eradication of the source of the infestation that is in the female and the location of the site of the infestation. Abstinence from sexual relations should of course be stressed during treatment.

Medical literature, especially the German, repeatedly describes a *Trichomonas* urethritis of long standing in which the prostate is not involved and the careful observations given seem to substantiate this. It would seem plausible, however, and my own observations and those of others would lead one to believe that if the infestation is one of long standing the prostate is the site of the infestation.

For urethral irrigations, Grimm,¹⁶ Balkow¹⁸ and others recommend mercuric oxycyanide 1:4,000 to 1:2,000. Riba recommends acriflavine hydrochloride, to which I am more favorably inclined.

Pelouze¹⁹ recommends prostatic diathermy, after which 1:3,000 acriflavine solution is injected into the bladder with a bulb syringe, also some of the solution is held in the anterior urethra for ten minutes. Pelouze states that no trichomonads have been found after the fourth treatment on alternate days, and in only one case was it present after the second diathermy. He insists, however, on six consecutive treatments and two more a week later.

Drummond¹⁷ advocates irrigating the posterior urethra with 1:8,000 metaphen and the injection of 3 cc of a colloidal silver preparation into the lateral lobes of the prostate, through a McCarthy panendoscope and specially devised intraprostatic needle.

For a better understanding of *Trichomonas* infestation, it may be said that the cycle of infestation is ostensibly different than in gonorrheal infection. In gonorrheal infection the female is infected by an infected male. She then infects other males. With *Trichomonas* no such condition exists. Here one is dealing with an infestation in which the exact mode of infestation is not clear but the incidence of which in both the married and the unmarried woman is comparatively high and not dependent to any large extent on sex relation for primary infestation. However, through sex relationships it may be transferred to a less fertile field in the lower urinary tract of the male.

Though the incidence of infestation in males is higher than statistics would lead one to believe, the difference of incidence between sexes is easily accounted for, anatomically by the close proximity of the rectum and vagina in the female and the less fertile field offered by the longer tubed male urethra, physiologically by the presence of the urinary stream in the male, biologically by the size and delicateness of the organism, pathologically by the comparative superficiality of the disease process, and finally by the fact that its widespread presence in the female is not dependent on sex relationships but possibly occurs by contamination from the intestinal tract.

FLUID POSTOPERATIVELY

A STATISTICAL STUDY

BERNARD FANTUS, M.D.

CHICAGO

Since physicians have learned to give fluid intravenously without immediate ill effects, streams of fluid, literally, have been pumped into the veins of defenseless patients with very little actual knowledge of what becomes of it or of them. A recent article by Cutter¹ shows that in this country the choice of the kind of fluid to be used is largely sectional and therefore probably irrational.

It is barely two years since the Cook County Hospital established its "Solutions Laboratory." Prior to this the "Drug Room" prepared these solutions with commercial distilled water, and the incidence of "reactions" was so high that the staff doctors were afraid to order them so that but little of these solutions was used.

Now there are no reactions due to the solutions, chiefly owing to the fact that water that has just been distilled—but only once distilled—is being employed, and that sterilization follows immediately on preparation of the solution. The Solutions Laboratory now dispenses over 7,000 flasks a month, and the consumption is still going up. Hypodermoclysis and rectal administration of fluid have become practically obsolete. Whether properly so demands investigation.

In an endeavor to determine what becomes of these solutions and to what degree patients are benefited or possibly harmed by them studies have been going on—since the inauguration of this service—to secure data that might be of value in drawing conclusions. The present report is given at this time, even though it raises more questions than it answers with the hope that it may inspire similar studies elsewhere, for it is necessary that some of these questions be answered promptly.

THE QUANTITY

The amount of solution introduced has varied from 2,000 to 7,000 cc. In chart 1 the quantities are shown in the abscissa, while the height of the column or the figure on top of it indicates the number of patients in each group and the black portion of each the number that died. The curve in the graph indicates the percentage of deaths in each group.

This and the other graphs give the gross statistics including all kinds of seriously sick patients as secured

¹⁹ Pelouze. P. S. Personal communication to the author.

From the Cook County Hospital. Essential help was given in this study by Stella F. Walker, medical statistician of the Cook County Hospital by the registered nurse Cora Oesterblom and by the technician Ann Kane.

¹ Cutter, R. K. The Use of Large Volume Intravenous Injections. *J. A. M. A.* 106: 1250-1252 (April 11) 1936.

from the "Recovery Ward," to which all these are sent after operation for a day's special care. It will be noted that the average mortality rate of all these patients is about 10 per cent. The total postoperative mortality at this institution is, of course, much less than this, as only the sickest patients get "Recovery Ward" service.

The most charitable interpretation one can give to this graph is that "the sicker the patient, the more fluid he gets." The other possibility is that the more fluid the patient gets the worse are his chances of recovery. The truth probably lies somewhere between the two extremes.

In these graphs two series (A and B) of more than one thousand cases each are shown. Series A was studied during approximately the first year and series B during the second year of this study.

That there is a danger of overwhelming a patient's system with fluid becomes evident when one contemplates the table and chart 2. The table gives the percentage of fluid eliminated in the urine in relation to the quantity of fluid ingested during the first twenty-four hours postoperatively. It will be seen that there is a progressive decrease in the percentage of fluid eliminated as the quantity of fluid administered increases.

Chart 2 shows that the mortality rate is the higher, the lower the percentage of fluid eliminated in relation to that injected.

From it one can see that the smaller the percentage of the injected fluid that is eliminated, the greater the mortality rate. For patients who eliminated less than 10 per cent, the mortality rate has been 23.4 and 19 per cent respectively in the two series, about twice the average mortality rate, and from there on it declines in an almost straight line. Why this should be so requires further study. There are at least three possibilities:

- 1 The very sick patient cannot eliminate fluid freely and the sicker he is the less he eliminates. The retained fluid may be harmful.
- 2 The patients may have lost so much fluid during or after the operation that they had to retain most of it and died in spite of liberal intake.
- 3 The patients who died may have come to the operating room in so serious a condition of hypohydration that no amount of fluid could save them.

The question then is: Did the patients who died get too much fluid, not enough of it, or not nearly enough, or would they have died anyway owing to the hopelessness of their condition?

The answer to these questions can come only from a careful analysis of suitable statistics. These are not at present available. It is only on the basis of such analysis that it will be possible to decide how much fluid patients should receive postoperatively.

This much can be said from the data available that the patients of the first group, those who eliminated less than 10 per cent of the fluid injected and who died, had received fairly liberal amounts of it, as shown by the table.

Percentage of Fluid Elimination as Related to Quantity of Fluid Ingested During the First Twenty-Four Hours Postoperatively

| Cc. of Fluid Administered | No. of Cases | Lowest % | Highest % | Average % |
|---------------------------|--------------|----------|-----------|-----------|
| 0-500 | 14 | 0 | 37.5 | 19.14 |
| 501-2,000 | 12 | 22 | 154.5 | 42.66 |
| 2,001-3,000 | 127 | 0 | 80 | 19.31 |
| 3,001-5,000 | 82 | 0 | 70 | 16.75 |
| 5,001- | 21 | 2.9 | 34.3 | 14.28 |

There is a progressive decrease in the percentage of elimination as the quantity of fluid administered increases.

As these quantities of fluid did not save the patients' lives, the question is: Might not a more moderate amount of fluid injected have put some of these patients into the second group, namely, those who eliminated 11 to 25 per cent of the injected fluid and whose gross mortality was only 11 per cent? It should be noted that the patients who received less than 500 cc of fluid lived. This was probably due to the fact that they were not very sick and that they had been given the fluid by mouth. Otherwise the doctor, in his anxiety, would have "pushed fluids" intravenously.

It should be pointed out here that, contrary to what one might expect, the intravenous injection of fluid is much less diuretic than is oral ingestion, for it is administration of fluid by mouth that is largely responsible for the cases of more than 100 per cent elimination of fluid shown in chart 2. All the patients with huge elimination (from 201 to 1,000 per cent) had fluid administered to them by mouth. All recovered, obviously because none of them were sick enough to demand parenteral fluid administration. That fluid absorbed through the alimentary tract has a diuretic quality has been shown previously (Starkenstein,² Dresel and Leitner³).

² Starkenstein E. Elimination of Water with Various Salt and H Ion Content. *Klin Wchnschr* 3: 1274-1275 (July 8) 1924.

³ Dresel, Kurt and Leitner Zoltan. Zur Physiologie des Wasserhaushalts. Veränderungen Flüssigkeitsaufnahme und ihre Beziehungen zur Milzfunktion und zur Diurese. *Klin Wchnschr* 7: 1362-1365 (July 15) 1928.

In all the graphs the black columns indicate the actual number of deaths in each group.

Chart 1—Mortality rate in relation to the quantity of fluid administered. The sicker the patient the more fluid he gets. Series A: 1,018 cases, 120 deaths. Series B: 1,016 cases, 108 deaths. Curve shows percentage of deaths in each group.

Chart 2—Mortality rate in relation to the percentage of fluid elimination to postoperative fluid intake. The sicker the patient the less of the injected fluid does he eliminate. Series A: 1,018 cases, 120 deaths. Series B: 1,016 cases, 108 deaths. Curve shows percentage of deaths in each group.

CHLORIDE

The relation of the death rate to postoperative chloride elimination is shown in chart 3, which again gives the two series of about 1,000 cases each of the first and second year's study respectively. Series A shows that the group of patients with less than 0.1 per cent of chloride in the urine that is passed after operation had a mortality rate of 75 per cent and that the mortality rate line then descends down to the lowest point in the 0.6 and 0.8 per cent groups respectively. From these points a tendency to a rise manifests itself.

It should be stated here that in the A series 5 per cent dextrose solution was the one most commonly used.

Series A

Series B

Chart 3—Relation of the mortality rate to postoperative chloride elimination. Series A—923 cases, 105 deaths. Series B—987 cases, 99 deaths. Curve indicates percentage of deaths in each group.

As it appeared from a study of series A that some of these patients might have died from salt starvation, the more or less routine use of a mixture of equal parts of physiologic solution of sodium chloride and 5 per cent dextrose was employed during the time the statistics were gathered for series B. This probably is responsible for the fact that the first group, the one passing less than 0.1 per cent of chloride in the urine, has almost disappeared. The relatively low mortality rate in this group in series B may be accidental and due to the small number of cases, for it will be noted that the height of the death rate line picks up and is 30 per cent in the second group, with elimination of less than 0.2 per cent of chloride in the urine, and that from there on the two graphs are similar to each other, with the exception that the rise in mortality rate in the range of the high percentages of chloride elimination

manifests itself more definitely. Apparently patients passing excessively concentrated urine also have a high mortality rate.

The high death rate in the low salt elimination groups may be due either to the patients who died not having been given enough salt, or not early enough, or that certain moribund patients are unable to eliminate salt in the urine.

The solution now used almost as a routine in this hospital contains 0.425 per cent sodium chloride and 2.5 per cent of dextrose. The total mortality rate of the two series (A and B) of chart 3 does not seem to favor this solution over that of pure dextrose solution. It may be that, as is shown by series B, lives that may have been saved at one end of the line were lost at the other end. There may be danger of overburdening the system with an excess of salt, as there also is danger from salt starvation.

As is shown by Cutter's article, the solution at present largely favored in this country is 5 per cent dextrose in physiologic solution of sodium chloride. Whether this is better than the solution employed at the Cook County Hospital remains to be demonstrated. A priori, there seems to be a decided possibility that such solution may introduce an unphysiologic amount of salt into the system. As each thousand cubic centimeters of fluid contains 8.5 Gm of sodium chloride, the patient who receives 5,000 cc of such solution would be given 42.5 Gm of salt in the twenty-four hours. This certainly seems an excessive ingestion for most patients. It is, on the other hand, possible that, in certain emergency operations on salt-starved patients, hypertonic solutions of sodium chloride, e. g., 3 per cent, might be of life-saving importance. Higher concentrations of salt should probably not be employed, because of their damaging effect on the intima of the vein, which favors the production of thrombosis.

SUGAR

The reason for the routine use of dextrose can probably be given on the ground of its importance in the prevention of starvation ketosis, for the postoperative patient is a starved patient. Common sense should dictate not to force more into the system than can be taken care of. Therefore, the moment the patient, receiving dextrose infusion, passes sugar in the urine it is obvious that his sugar tolerance has been overwhelmed. The sugar thus wasted gives no concern because sugar is cheap, but along with it there is wasted a considerable amount of the fluid that has been introduced with it, as each gram of sugar eliminated takes 20 or more cubic centimeters of fluid with it.

No one seems to know what the average sugar tolerance of the postoperative patient is. It is probably a highly individual matter. It is certainly not the average sugar tolerance of the normal individual, as is shown by chart 4, from which known cases of diabetes have been excluded.

It will be seen (chart 4, part B, solid line) that the more sugar that is injected the greater the percentage of sugar-positive urines. It will be noted from this line that about one third of all patients given between 100 and 149 Gm of dextrose in the twenty-four hours eliminated sugar in the urine. As this solution is injected in a routine way by means of drip phlebotomy and we are dealing with adult patients, it is obviously less than the accepted sugar tolerance for normal individuals, which on the basis of the work of Woodyatt,

Sansum and Wilder⁴ has been assumed to be above 0.8 Gm and below 0.9 Gm per kilogram of body weight hourly. Were this true a person weighing 70 Kg should tolerate 63 Gm of dextrose per hour.

The group given between 150 and 199 Gm in the twenty-four hours had glycosuria in more than one third of all cases, and in the group given above 200 Gm one half of all patients passed sugar. Chart 4 shows that the total mortality rate increases suddenly when the intake of 100 Gm is exceeded.

That this is not due to the loss of sugar in the urine is shown by part B chart 4 broken line which shows that the patients whose urine was sugar positive curiously enough had a lower mortality rate in the highest brackets than those who were sugar negative.

Part C, chart 4, broken line which indicates the percentage of deaths in those whose urines were sugar negative, rising as it does progressively as the quantity of sugar given increases points to one of two possibilities. Either this is due to the fact, first established in this study that "the sicker the patient, the more fluid he gets" or else there is intrinsic harm in giving very sick patients a large quantity of sugar. Even if the first-mentioned proposition is true it can be concluded that the large ingestion of sugar did not do them any good for all of the patients being discussed died.

RECOMMENDATIONS

Excepting in emergency hypohydrated and salt-starved patients must not be sent to the operating room. If it were a standing order that no patient should be sent to the operating room unless he had passed at least 1500 cc of urine in the preceding twenty-four hours and this urine contained at least 0.5 per cent of chloride, this requirement would be automatically met.

Patients who cannot be prepared in this way for the operative ordeal should receive special care during, as well as after operation to minimize the disadvantage from which they are suffering.

Patients who have undergone serious operations should have a salt and fluid balance sheet established for them in which the quantities of fluid administered and of urine eliminated are carefully recorded and a balance is struck at least every twelve hours to warn the attending physician of approaching danger.

The salt elimination in the urine should be estimated postoperatively and we have a very simple, roughly quantitative test for this purpose that can be carried out by any trained nurse or other intelligent person.

SIMPLE QUANTITATIVE CLINICAL TEST FOR CHLORIDE IN URINE

Place 10 drops of urine in a test tube. Add 1 drop of a 1 to 5 potassium chromate solution. The fluid will now assume a somewhat distinctly yellow color. Add drop by drop with the same dropper or one of the same caliber, a 29 per cent silver nitrate solution until a permanent and distinct color change to red-brown occurs (resulting from the formation of silver chromate). The number of drops required to produce the change of color expresses in grams the content of chloride per liter of urine.

Sugar should also be tested for in the urine not only preoperatively but postoperatively as well, and the

qualitative test probably suffices. When sugar is found to be present in the urine of a patient who is given dextrose, it is an indication that the patient is receiving more dextrose than he can take care of. If the patient is receiving large quantities of dextrose the obvious indication is to reduce the intake. If his intake has not been excessive, the administration of insulin may possibly be life saving, for some of these patients may have been rendered temporarily diabetic.

Such studies as these must be carried on extensively to answer the various questions raised as well as others that have not been touched on e.g., that of alkali balance before we may consider ourselves able to secure the maximum benefit with the minimum harm from this relatively new therapeutic measure. One thing is certain—less routinism and more individualization is desirable. Even if subsequent studies show that the mortality rate statistics were due to the patients' condition rather than to the use or nonuse of solutions, the data given are of value from a prognosis standpoint.

Chart 4—Relation of the mortality rate to sugar intake and elimination. The more sugar the patients get and the higher the mortality rate the more of them eliminate sugar in the urine. Part A Cases tested for sugar 844 deaths 74. Curve indicates percentage of deaths in each group. Part B Sugar positive cases 129 deaths 7. Solid line indicates percentage of sugar positive cases in the entire group of cases (844). Broken line indicates percentage of deaths in sugar positive cases. Part C Sugar positive cases 715 deaths 67. Solid line indicates percentage of sugar negative cases in the entire group of cases (844). Broken line indicates percentage of deaths in sugar negative cases.

CONCLUSIONS

- 1 There is a tendency among surgeons to give the more fluid, the sicker the patient.
- 2 The smaller the percentage of the injected fluid that is eliminated the greater the mortality rate.
- 3 Excessively low or excessively high salt elimination in the urine passed postoperatively carries with it a relatively high mortality rate.
- 4 The more dextrose that is injected, the greater the percentage of sugar-positive urines. The sugar tolerance of the patients after operation is less than that of the normal individual.
- 5 Proper preoperative preparation of the patient demands prevention of hypohydration as well as of salt starvation.
- 6 Postoperative use of fluids, to be properly individualized, demands observation of balance between fluid intake and fluid elimination, the determination of the percentage of chloride in the urine and the testing for the presence in it of sugar.

CALCIFICATION OF THE AORTIC VALVE

L MINOR BLACKFORD, MD

WILLIAM W BRYAN, MD

AND

EMORY D HOLLAR, MD

ATLANTA, GA

Calcification of the aortic valve is not a newly discovered condition although one might gather from the recent literature that it was first described by Monckeberg in 1904. William Cowper¹ in 1706, however did not consider it unusual. He reported, in the case of "a spare man about 30 who languish'd with an Ulcer in the Thigh, attended with a Caries or Rottenness of that Bone at its Articulation with the Tibia and Patella, The three Semilunary Valves of the Aorta were somewhat thicker and not so pliable as naturally owing to a Bony or stony body." He described also the case of another man of about 40 whose "Left Ventricle was found larger than that of an ordinary One." The Valves of the Great Artery were Petrify'd, inasmuch that they could not approach each other. But an Orifice remain'd always open by the Petrifications." We have seen no more beautiful illustrations of the gross appearance of calcification of the aortic valve than those Cowper presented in 1706.

Excellent descriptions were also recorded by Vieussens² in 1715 and Morgagni³ in 1769.

Osler⁴ was quite familiar with calcification of the aortic valve at the time of the first edition of his textbook (1893). He recognized that it was much more common in men, usually elderly men. He proposed to divide the cases into "two groups, those with and those without arteriosclerosis." In discussing aortic incompetence, he said "Long before any signs of fail-

ing compensation, pain may become a marked and troublesome feature.

Attacks of true angina pectoris are more frequent in this than in any other type of valvular disease.

Sudden death is frequent." In regard to aortic stenosis, he wrote "The older the patient the more likely it is that the valves will be rigid and calcified.

Palpation reveals in many cases a thrill

Fig 1—Teleoroentgenogram on Dec 10 1935. Tremendous hypertrophy of the left ventricle is shown. The transverse diameter of the heart is 19.3 cm, the transverse diameter of the chest is 28.9 cm.

at the base of maximum force in the aortic region. With no other condition do we meet with thrills of greater intensity." In his fourth edition (1901) Osler was more specific about rheumatism. "The valvulitis of rheumatism, while less rarely aortic, is common

enough in children, and insufficiency is caused by nodular excrescences at the margins or in the valves, which may ultimately be calcified." Further, he wrote, "in the endocarditic group in which the valve segments are united and often covered with calcified vegetations and excrescences, the systolic murmur is rough and may be accompanied by a thrill."

Interest in calcification of the aortic valve was revived five years ago with a report of forty-two cases observed at necropsy by Margolis, Ziellessen and Barnes.⁴ This was quickly followed by a discussion of the clinical aspects by Christian⁵ who announced that Sosman had perfected a technic for demonstrating

Fig 2—Multiple areas of calcification lying in the region of the aortic valve. Right anterior oblique view.

the calcification under the fluoroscope. Sosman and Wosika⁶ two years later described the roentgenologic technic in detail and reported twelve cases diagnosed in life. In 1934 Sparks and Evans⁷ added a case, as did Cooley.⁸ Last year Willius and Camp⁹ in a second paper from the Mayo Clinic announced the diagnosis during life of fifteen additional cases. It would appear that less than fifty cases of calcification of the aortic valve diagnosed during life have been reported in the literature and few have been followed to necropsy.

Boyd¹⁰ has said "The cusps of the aortic valve may be thickened, adherent to one another and

calcified. When this is associated with a similar lesion in the mitral valve it is probable that the condition is secondary to rheumatic endocarditis. Although it is not possible to be certain, it appears probable that the calcified nodular group is also due to a preceding rheumatic infection."

REPORT OF CASE

A well developed Negro aged 36 came to the dispensary on April 8, 1935, complaining of shortness of breath and swelling of the legs for several months and of pain in the chest over a number of years. This pain would come on after exertion, particularly after coitus, or at night following a full day's work. It began just within the left nipple and radiated up across the sternum often involving the left arm. Twice the pain had been so severe that he thought he was going to die. The pain, with palpitation and shortness of breath lasted usually from one to three hours. These attacks had been growing more frequent and more severe and since August 1934 there had been some edema and nocturnal cough.

Precordial bulging, a diffuse, heaving apical impulse and pulsation in the vessels of the neck were seen. Great cardiac hypertrophy and a systolic thrill at the base were also noted. The systolic blood pressure was 146, the diastolic 42, the pulse was 108. There was a loud, harsh systolic murmur in the second right interspace, transmitted across the sternum and up into the carotids. A diastolic murmur was loudest in the third interspace at the left border of the sternum. Slight pulsation was noted in the retinal arteries, which showed a minimal degree of sclerosis (Dr J R Paulk).

The electrocardiogram showed a rate of 100 with a normal rhythm. The PR interval was 0.24 and the QRS 0.12. In lead I the T wave was inverted, and in leads 2 and 3 the S wave was deep.

A diagnosis of aortic incompetence was made and symptomatic treatment instituted.

In May the patient was admitted to a veterans' hospital in another city. He was discharged November 23 and three days later he returned to the Grady Hospital. He said that the edema had cleared up promptly but that the "misery" over the heart and the aching in the left arm had persisted. At this time a more detailed history was secured. He had enjoyed perfect health until 1918, when on account of pruns in the ankles he

vigorous and "rocking." Viewing the cardiac shadow in the region of the atrioventricular junction through a small aperture revealed several distinct areas of calcification. These lay high and just to the left of the border of the spine in the direct postero anterior projection in the middle third and just above

Fig 3—The heart. The left ventricle occupies about three fifths of the anterior surface of the heart. Along the outer border of the left ventricle adherent pericardium has been turned back.

was admitted to an A E F hospital. On dismissal after six weeks he was told that there was "a little something wrong" with his heart. While at work in 1923 he suddenly became dyspneic and experienced dull aching over the heart, that night he suffered severe pain near the apex with orthopnea lasting about an hour. He was then able to make a living without much difficulty for the next six years in spite of occasional heart attacks, many aches and pains in his joints and back, and repeated gonorrhea. In October 1929 he was admitted to the urologic service. A junior intern noted, "over the aortic region the second sound is not heard, but there is a continuous blow until the next systole." The blood pressure was 116/60. After this cardiac symptoms varied sometimes for six consecutive months they would be mild. He consulted other physicians and several times entered government hospitals before returning to the Grady Hospital in 1935. "Fifty Wassermanns" had been reported negative.

In view of the long history, the intense thrill and the harshness of the systolic murmur in the aortic area, one of us thought that calcification of the aortic valve was present and referred him for roentgenologic verification.

Roentgenoscopy according to Sosman's technic showed marked cardiac enlargement, particularly of the left ventricle. The left atrium was not enlarged. The beat was regular,

Fig 4—Roentgenographic appearance of the heart post mortem. A heavy wire ring is in the aorta just above the calcified valve. A fine wire separates the right border of the right ventricle from the atrium. The second wire was accurately placed at the left border of the right ventricle on the anterior surface. Note the thickness of the walls of the left ventricle.

a line drawn through the cardiac shadow along the atrioventricular junction in the right anterior oblique, and high and anterior in the left anterior oblique. The components of calcification moved synchronously and quickly toward the shadow of the base with each systole and returned slowly

Fig 5—The aortic valve from above. Arrows point to the peaks of the commissures. The right cusp, the left cusp and the posterior cusp are indicated by R.C., L.C. and P.C. respectively. The edges of the right cusp are largely obscured and the cavity of each cusp is black with retained blood. Note that the aortic intima is smooth and glistening. Natural size.

toward the apex in diastole. The aorta was normal. The shadows were recorded in films exposed one-twentieth second (fig 2). The diagnosis of calcification of all cusps of the aortic valve was made.

The patient was not willing to enter the hospital for intensive study until frightened by an anginal attack on Jan 21, 1936. During the two weeks of hospitalization, systolic blood pressure

ranged from 120 to 180, and the diastolic from 40 to 60. A second electrocardiogram revealed that the PR interval had increased from 0.24 to 0.36 second. Other reports were without interest.

On the night of March 30, after working all day, he suddenly complained of excruciating precordial pain and shortness of breath. He was dead when his car reached the hospital.

Fig 6—Axial roentgenogram of the excised aortic valve. Pins have been inserted to divide the cusps as in figure 5. The pin pointing to *A* lies in the right coronary artery, the pin pointing to *L* is in the left coronary artery but its point should be 16 mm lower to indicate direction of the artery. Natural size.

Necropsy was done after embalming. Except for evidence gross and microscopic of chronic passive congestion interest was confined to the heart. The heart weighed 1070 Gm. It measured 17.5 cm from apex to base, 13.5 cm across the base

Fig 7—Myocardium under low power. Note the extensive fibrosis.

and 11 cm through the base. The left ventricle occupied about three fifths of the anterior surface, the apex of the right ventricle did not come within 5 cm of the apex of the heart. The greatest width of the right ventricle on the anterior surface was 6.5 cm. Just posterior to an artery on the border of the left ventricle a branch of the anterior descending ramus of the left coronary, the pericardium was adherent for 5 cm. The atria were neither dilated nor hypertrophied, the wall of each

averaging 4 mm in thickness. The foramen ovale was patent, forming a slit of 8 mm. The normal tricuspid valve measured 12 cm. The cavity of the right ventricle was small from the tricuspid ring to its apex measured but 7 cm. The conus arteriosus was prominent. The pulmonic valve was normal, its inner circumference measuring 9.4 cm.

The mitral ring measured 9 cm; the valve was thickened and scarred but not calcified. From the ring to the apex of the cavity measured 11 cm. The wall of the left ventricle and the interventricular septum was from 2 to 3 cm thick. The muscle was firm and there was irregular scarring throughout. The commissures between the aortic cusps were adherent and densely calcified (figs 5 and 6). The free edges were rolled and thickened but even after embalming could be moved 1 or 2 mm. The coronary ostia were widely patent but just distal to them there was sharp angulation of both arteries. The inner circumference of the right coronary 1 cm from the aorta measured 13 mm. Just proximal to the bifurcation of the left coronary its inner circumference also measured 13 mm. The branch adjoining the adherent pericardium was greatly nar-

Fig 8—Appearance of an Aschoff nodule under high power.

rowed if not occluded but otherwise the coronary arteries showed no gross lesion. The inner surface of the aorta just above the valve measured 9.3 cm. The ascending aorta was smooth and glistening without gross changes. 2 cm above the valve it measured 8.3 cm. Just distal to the origin of the left subclavian the inner circumference of the descending aorta was only 4.4 cm.

Histologic study of the myocardium (by Dr Jack C. Norris) showed extensive fibrosis characterized by proliferating fibroblasts with a few lymphocytes (fig 7). Fusiform groups of fibroblasts intermingling with atypical epithelioid cells (fig 8) were diagnosed as quiescent Aschoff bodies.

COMMENT

Osler first divided cases of calcification of the aortic valve into "those with and without arteriosclerosis." In this case arteriosclerosis was singularly lacking in the retinal and coronary arteries, and in the aorta. From the history and microscopic studies we feel justified in saying that it belongs to the group Osler described as of rheumatic origin. We have diagnosed but one other case of calcification of the aortic valve, and this was in a man of 59 who is still living; it was typical of the

more common type. A calcified aortic valve is a matter of importance in differential diagnosis because in the South as soon as an aortic diastolic murmur is detected, particularly in a Negro, we are only too apt to make a diagnosis of syphilitic aortic insufficiency. One of us has studied more than 140 cases of the syphilitic type of valvular involvement but has not heard such a harsh murmur in any of them, nor has the occasional aortic thrill (noted by Corrigan) even been so intense.

The electrocardiograms gave evidence of severe myocardial damage and a serious prognosis. The "T-1 and S-2 combination" remarked on by Proger and Minnich, the bundle branch block and the increase in the PR interval.

It has often been said that the Negro is not subject to angina pectoris. Aside from the frequency of retrosternal pain in syphilitic cases we have noted cardiac pain in a number of cases of hypertension and arteriosclerosis and in one case of biventricular aorta with pulmonic stenosis. We have also seen several cases of angina in rheumatic heart disease although rheumatic heart disease is not common in Atlanta. This patient suffered from classic angina pectoris.

SUMMARY

In a Negro aged 37 with a long history of cardiac pain and a relatively short history of congestive heart failure the diagnosis of calcification of the aortic valve was made during life.

DURATION OF FRACTURES AND OPERATIVE DEFECTS OF THE SKULL

AS REVEALED BY ROENTGENOGRAMS

(A FOLLOW-UP STUDY OF ONE HUNDRED PATIENTS)

MARK ALBERT GLASER M.D.

AND

EDWARD S. BLAINE M.D.

LOS ANGELES

The persistence of skull fractures and other cranial defects over a period of years as visualized by the roentgenogram, is not only of medicolegal importance but of great academic interest. In order to obtain some idea of the reaction of the skull to traumatic and surgical defects, 100 cases have been studied by repeated x-ray examination over a period of from one to ten years. Certain technical difficulties have arisen in this follow-up study, mainly the taking of x-ray films at similar angles of the original and the utilization of similar tube distances, milliamperage and voltage, as well as the time and temperature for film development. In certain shelving fractures or some depressed fractures great difficulty of x-ray detection was encountered because of the obliquity to the line of cleavage which necessitated the taking of numerous films. Attention was concentrated on all these points of technic, and efforts were exerted to duplicate such technic as nearly as possible. These traumatic and surgical defects which comprise this series, have been classified as follows:

1 Linear fractures

- (a) Linear fractures under 5 years of age
- (b) Linear fractures in adults

2 Depressed fractures

- (a) Depressed fractures without elevation of fragments
- (b) Depressed fractures with elevation of fragments
- (c) Depressed fractures fragments hammered out
- (d) Depressed fractures, fragments removed

3 Operative defects

- (a) Simple decompressions
- (b) Bone flaps with degeneration
- (c) Bone flaps without degeneration
- (d) Regeneration of osteoperiosteal graft
- (e) Degeneration of bone islands left in skull defects

LINEAR FRACTURES

(a) *Children*—In this series there are fifty patients with linear fractures, five of these occurring in children under the age of 5 years and the other forty-five in adults ranging in age from 18 to 58 years. In all the children the linear fracture entirely disappeared within six months after injury. On rare occasions the skull around the fracture becomes absorbed and a large bony defect becomes apparent. None of the cases in this series showed this situation.

Fig. 1—Linear fractures in a child

A child, aged 2½ years, fell from a two story window and was unconscious for two days (fig. 1). The original film reveals a linear fracture crossing the superior portion of the left and right frontal bone extending backward into the parietal bone, another linear fracture was present in the left parietal bone and extended into the squamous portion of the temporal bone thence into the base. Films taken five and a half months later failed to demonstrate any evidence of fracture.

(b) *Adults*—In the forty-five adults, very definite variations occurred. In one patient the x-ray evidence of fracture existed five years after injury, but films taken eight years after injury showed a complete disappearance. In another patient the disappearance of x-ray evidence was complete within a year after injury. In the majority of cases, however, fading of the fracture line commenced approximately eighteen months after injury and the fracture entirely disappeared in approximately four years. This marked variation in adults may be explained by the difference in the depth of the fracture as well as the amount of separation. A man, aged 45, was injured in an automobile accident. He was rendered unconscious and remained irrational for a period of four weeks. Roentgenograms taken Oct. 13, 1930, revealed a linear fracture of the left parietal bone, extending to the anterior part of the squamous portion of the temporal bone. A roentgenogram taken April 17, 1933, some two and a half years

11 Proger S. H. and Minnich W. R. Left Axis Deviation With and Without Heart Disease. *Am. J. M. Sc.* 189, 674-681 (May) 1935.
Read before the Radiology Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13 1935.

later, revealed a definite fading of the fracture but evidence of its existence was still present. This is characteristic of the usual skull fracture.

DEPRESSED FRACTURES

(a) *Without Elevation*—Depressed fractures have been divided into four groups each of these groups comprising six or less cases. A man, aged 57, fell from

Fig. 2—Note rounded appearance of depressed area.

a two-story building striking his head and was rendered unconscious. Films taken immediately after the injury revealed a depressed fracture of the temporo-

Fig. 3—Depressed fracture with fragments removed. The size of the defect is the same after a period of seven years.

parietal regions. Elevation was not carried out. Approximately a year and two months later x-ray films were again taken. In the lateral view the line of fracture had entirely disappeared. In the postero-anterior view (fig. 2) the rough lines are rounded and the appearance of a complete union of the fragments is

apparent. In these cases the roentgenographic evidence reveals extreme pathologic change, but in spite of this the fracture seems to heal better, roentgenographically, than a simple linear fracture. It is possible that the overlapping of bone and the close approximation of these depressed fragments are responsible for a more compact bony union than occurs in the linear cases.

(b) *Depressed Fractures with Elevation of the Fragments*—In this series of cases the fragments were elevated into position. None of these were removed. In all these cases evidence of depression or evidence of fracture were entirely obliterated in from two to four years. In the case of a man aged 29, receiving a depressed fracture of the right parietal region elevation was carried out. X-ray films taken four years later revealed entire disappearance of the fracture line with complete bony union.

(c) *Depressed Fractures with Fragments Hammered Out*—A man aged 38 was struck on the head by a timber receiving a large depressed fracture in the right

Fig. 4—Degeneration of a bone flap. Linear fracture present.

parietal region. A bone flap was turned down and the fragments were hammered out. Films taken nine months after the injury showed no evidence of depression with a complete disappearance of the fracture lines. Films taken four years later were the same, the flap being normal and showing no evidence of degeneration.

(d) *Depressed Fractures with Fragments Removed*—In cases with depressed fractures in which the fragments were removed the bony defect persisted (fig. 3). A man aged 32, was injured in an automobile accident, receiving a compound comminuted depressed skull fracture. The fragments were elevated and removed. Films taken seven years later differ in no way from the films taken shortly after operation, excepting that the bony edges have become smoother, the size of the defect has not decreased in any way.

OPERATIVE DEFECTS

(a) *Simple Decompressions*—Simple decompressions act similarly to depressed fractures with the removal of fragments. The bone never fills in and the edges become smooth and rounded. Cases in this series have shown bony defects extending as long as thirty years.

(b) *Bone Flaps with Degeneration*—A man, aged 29, was struck on the head with a blackjack, receiving a linear fracture of the skull. A subdural hematoma developed shortly afterward, for which a bone flap was turned down in another clinic. Films taken four months after surgery revealed a linear fracture as well as osteolytic changes in the entire bone flap with osteoporosis and large areas of complete disappearance of bone structure (fig 4). Films taken five and a half years after injury revealed a progressive loss of bone structure in the bone flap. Only a few islands of bone still remained and the fracture line had disappeared (fig 5). On palpation there is no evidence of softening, and the bony covering is firm and solid.

(c) *Bone Flap Without Degeneration*—Osteoplastic bone flaps of the skull turned down for tumor or hemorrhage usually do not degenerate. In this series of cases the majority appeared entirely normal and the outline was always apparent on the roentgenograms up to ten years after operation, the longest lapse of time in our series. On autopsy and secondary surgery no evidence of calcification or bony union was found between bone flap and skull. The flap was firmly held in place and united to the skull by heavy bands of fibrous tissue.

(d) *Regeneration in an Osteoperiosteal Graft*—A man aged 38 had a compound comminuted depressed fracture of the vault with a subsequent development of an extradural abscess. The depression was elevated, the fragments were removed and the abscess was drained. The patient made an uneventful recovery. One year later (fig 6) an osteoperiosteal graft was placed in situ. Films taken from time to time revealed a gradual formation of bone over the graft. The graft at all times was firm and solid.

Fig 5—Increasing degeneration of bone flap. Disappearance of fracture five and a half years after injury.

(e) *Degeneration of Bone Island Left in a Depressed Fracture*—A man, aged 43, was struck on the head by an iron hook, with a resultant depressed skull fracture, which was elevated in another clinic. Some of the fragments of bone were left in situ. Films taken two years later revealed a progressive absorption of these fragments. Palpation did not reveal any evidence of softening or irregularity.

From this study it will be seen that skull fractures heal quite differently than do fractures of the long bones. No visible callus forms and the healing is affected by the formation of connective tissue, which slowly becomes osseous as the result of the slow deposit of inorganic material. In none of these cases has there been any radiographic evidence of callus formation.

Fig 6—Fragments removed at first operation. An osteoperiosteal graft inserted. Note formation of bone islands in the graft.

The presence or absence of skull fracture, as visualized by the x-rays is of little or no importance in the prognosis of the case. We are primarily interested in brain injury and not skull fracture. The presence of fracture, however, is positive evidence that a definite blow has been struck and that an injury has been received. Thus radiographic evidence of fracture is an aid in eliminating malingering. Unfortunately, the public, including attorneys, place altogether too much emphasis on the existence of a fracture line. The results of this study will be of great aid in determining the difference between an old and a recent fracture. Furthermore, when there is a question of doubt as to the presence of fracture, films taken at a later date will help to show the status of the particular shadow in question.

From this study it is quite apparent that x-ray films taken from eight months to several years after injury are of equal value to those taken immediately after the injury in determining the presence or absence of skull fracture.

CONCLUSIONS

1. Linear fractures in children under 6 years of age disappear within six to twelve months after injury.

2. In the minority of cases, linear fracture in adults begins to fade from six to nine months after injury and disappears in from twelve to eighteen months. The majority, however, show fading from eighteen to twenty-four months after injury and entirely disappear from four to five years, rarely longer.

3. In depressed fractures without elevation, the fragments become rounded and unite, and the lines of fracture cannot be detected, though the depression is apparent.

4. In operative defects wherein the bone has been removed, or in cases of depressed fracture wherein the fragments have been removed, the cranial defect never becomes smaller, the only change being a rounding of the edges.

5 Bone flaps may either undergo absorption or appear normal

6 Bone grafts properly placed form a definite covering over the defect

7 In medicolegal cases of old and recent injury the approximate age of the existing line of fracture may be determined

8 The status of questionable fracture lines may be determined by their fading and disappearance

9 X-ray films taken from six months after injury in children to nine months after injury in adults are as valuable as those taken immediately after injury in determining the presence or absence of fracture

BENZEDRINE SULFATE AND ITS VALUE IN SPASM OF THE GASTRO- INTESTINAL TRACT

ABRAHAM MYERSON M.D.

AND
MAX RITVO M.D.
BOSTON

The problem of the muscular activity, normal and abnormal, of the gastro-intestinal tract is one that has intensely engaged the attention of physiologists, roentgenologists and clinicians. The alimentary canal is so linked up with the emotional state of the human being that every profound disturbance in mood, particularly any sudden shock of fear or disagreeable emotion is associated with marked changes in the activity and tonus of the digestive tube. This set of hollow organs rivals the circulatory system in its relationship to the affective life of man. Abnormal motor activity, especially spasm, is definitely caused by organic disease of the gastro-intestinal tract and, too, the gastro-intestinal tract responds by spasm and abnormal motility reflexly to diseases of other structures of the body. It is especially with spasm of functional organic and reflex type that we have concerned ourselves in this paper.

We shall not discuss in detail the physiology of the muscular activity of the gastro-intestinal tract. This is very complicated and in many particulars is still obscure. It may be stated that in a general way the action of the parasympathetic nervous system and of drugs of the parasympathomimetic type such as mecholyl and physostigmine increases the tonus and peristaltic activity of the stomach and intestine. On the other hand, the action of the sympathetic nervous system and of drugs of the sympathicomimetic group is to decrease tonus. This is true only as a general statement and has many exceptions, which depend mainly on the fact that these two divisions of the autonomic nervous system are in a state of equilibrium. Disturbances of the delicate balance between these two portions of the autonomic mechanism may be as important as sympathetic or parasympathetic stimulation. Also it is well established that the type and degree of stimulation, and the antecedent state of the organs before the application of the stimulus, play a very important part in determining the final result in increase or decrease of tonus and peristaltic activity.

Spasm in the gastro-intestinal tract is a major clinical problem, it is particularly important to the roentgenologist, as it occurs frequently and since it may be a very confusing and annoying factor in the roentgen examination of the stomach and intestine. Spasm may involve any part of the alimentary canal or several portions simultaneously, it may be of any degree, from slight and superficial to deep and extensive contractions, it may be of fleeting duration or persist intermittently or constantly for long periods of time. The deformities caused in the stomach and intestine by reflex or functional spasm may closely simulate organic disease and often make accurate roentgen diagnosis difficult or actually impossible. In other instances, spastic manifestations may mask or obscure the true pathologic process and lead to incorrect conclusions.

Spasm originates from diverse causes. It may result from (1) functional disturbances such as worry, dislike of the opaque meal, fear caused by the darkness and surroundings of the roentgenoscopic room, apprehension as to the result of the roentgen examination, and other psychologic factors, (2) the neuroses and psychoses, (3) intrinsic disease of the gastro-intestinal tract for example, cancer, peptic ulcer or appendicitis, and (4) extra-alimentary conditions such as renal colic, plumbism or tabes dorsalis.

Roentgenologists and clinicians have long felt the need of a drug or other means of abolishing spastic manifestations in the gastro-intestinal tract. If the spasm is due to psychologic factors reassurance is effective in a small percentage of cases. Massage of the abdomen and pressure over the stomach and intestine with the gloved hand during the roentgenoscopic studies may at times lessen or abolish the spasm, if there is local tenderness or rigidity of the abdominal muscles, these measures cannot be applied. Many drugs, particularly atropine and benzyl benzoate, have been used, but it is generally agreed that these are unavailing and their use has been practically abandoned.

Fig. 1—A before the administration of benzedrine sulfate the pylorus was markedly spastic. The duodenum filled only partially and the stomach emptied very slowly. B after the drug was given the spasm disappeared in about ten minutes and the pylorus and duodenum filled normally.

As discussed in a previous communication by Ritvo and Weiss,¹ a drug or other antispasmodic method which is to be of value to the clinician and roentgenologist should have the following characteristics: (1) The effect should be of sufficient duration to permit of thorough study, yet not unduly prolonged, (2) it should not cause unpleasant or dangerous reactions, (3) it should be rapidly and uniformly effective when

Read before the Boston Society of Psychiatry and Neurology, March 19, 1936.

The authors are indebted to Smith, Kline & French Laboratories for their generosity in supplying the benzedrine sulfate.

given orally, as some patients may object to injection methods, (4) the routine roentgen studies should not be interfered with and (5) it should be generally available and inexpensive.

We have studied the effect of benzedrine on the spastic states of the gastro-intestinal tract. Benzedrine is a synthetic derivative of ephedrine with the chemical formula $C_{10}H_{15}CH_2CHNH_2CH_3$. In the form of benzedrine sulfate it is stable and can be administered orally. It causes stimulation of the sympathetic nervous system and has been used successfully in the treatment of narcolepsy. Our study definitely demonstrates that benzedrine sulfate in nontoxic doses lessens or abolishes spastic manifestations of the gastro-intestinal tract within a few minutes.

In cases of pylorospasm, roentgen examination may be greatly interfered with, the opaque meal leaves the stomach only after considerable delay and then may pass out in such small spurts that the sphincter and duodenum do not fill sufficiently for satisfactory roentgenoscopic visualization. Ulcer craters and other pathologic processes may therefore be obscured and until the spasm disappears there is no way to determine with

Fig 2—The examination before the drug was given revealed *A* a small contracted and irregular duodenum. There was spasm of the pylorus and duodenum with very slow emptying of the stomach. The manifestations suggested ulcer, however the duodenal outline was so poorly visualized that a positive diagnosis was not possible. *B* after the ingestion of 30 mg of benzedrine sulfate the spasm relaxed and the opaque meal filled the pylorus and duodenum clearly demonstrating a duodenal ulcer. Note that the stomach shows good tonus and peristaltic activity under the influence of the drug.

certainly whether or not there is intrinsic disease in the region of the pylorus. After the administration of benzedrine sulfate, the relaxation of the sphincter permits the passage of a broad stream of the barium sulfate mixture through the pylorus and duodenum. The nature and extent of the pathologic process may then be demonstrated with greater certainty and with saving of time and energy to both the patient and the physician, or, if the defects and irregularities that were present disappear under the influence of the drug, the presence of local disease can be definitely excluded. The drug has shown itself to be of especial value in the diagnosis and localization of peptic and duodenal ulcer. During the routine roentgen studies it is frequently impossible, even after the most careful and prolonged observation, to state more than that the pylorus and cap are contracted and fill irregularly. We have on numerous occasions in this type of case clearly demonstrated a definite ulcer crater after the administration of benzedrine sulfate.

Gastric tonus is affected to some extent by the drug, the effect being to lessen the tone moderately. Stomachs that were previously hypertonic become more nearly normal in this respect. The stomach with normal

or poor tonicity may, however, show little if any change. Peristaltic activity is diminished slightly, if at all, after the administration of benzedrine and in some instances may be increased. We had expected that a drug which abolished spasm would at the same time cause atonicity and a marked decrease or absence of peristaltic activity. This would be of distinct disadvantage both to the roentgenologist, who depends greatly on peristalsis in

Fig 3—The examination revealed *A* a narrow, irregular pylorus with unsatisfactory visualization of the duodenum. Peristalsis was active but only very small amounts of the opaque meal passed through the sphincter during prolonged fluoroscopic observations. *B* after the administration of benzedrine sulfate the pylorus and duodenum filled well and the stomach emptied rapidly. An ulcerous crater in the region of the pylorus was distinctly visualized.

determining the constancy and extent of filling defects and irregularities in the stomach and duodenum, and to the clinician, who naturally does not wish to substitute atonicity and inertia for spasm. For example, during roentgen examination peristaltic waves pass through areas in which there is a filling defect due to extrinsic pressure or spasm, whereas with intrinsic lesions the waves are arrested or completely broken on reaching the process in the stomach wall. Therefore the fact that peristaltic action is not interrupted by benzedrine sulfate is of great clinical importance. The stomach actually empties more rapidly than normally under the influence of the drug, the relaxation of the

Fig 4—The examination without an antispasmodic revealed *A* a moderate degree of pylorospasm and a defect on the lesser curvature side of the duodenal cap which appeared constant. *B* after the giving of 30 mg of benzedrine sulfate orally a broad stream of the opaque mixture passed through the pylorus and duodenum and the deformity of the duodenal cap disappeared. The second and third portions of the duodenum showed angulation and displacement caused by adhesions from the gallbladder.

sphincter allowing the food to pass out of the stomach more rapidly than normally. This is in direct contrast to observations after the administration of ephedrine.²

2 Van Liere, E. J., Lough, D. H., and Sleeth, C. K. The Effect of Ephedrine on the Emptying Time of the Human Stomach. *J. A. M. A.* 106: 535 (Feb. 15) 1936.

In the intestine, the effects are similar in character to those described in the stomach. After the administration of benzedrine sulfate the lumen of both the large and the small bowel is increased, the haustrations become broader and shallower, and contractures or irregularities due to spasm diminish markedly or disappear entirely. The barium enema examination in cases of spasticity of the colon can be carried out more

Fig. 5—The film before benzedrine was given showed *A* irregularity of outline and narrowing of the pyloric region. *B* after the drug was taken a large irregular filling defect typical of carcinoma involving the distal third of the stomach was clearly outlined. The extent and character of the lesion are visualized with much greater clarity and the diagnosis is made more certain by the use of the benzedrine sulfate.

rapidly and with much less discomfort to the patient when benzedrine sulfate is used, as the patient is enabled to retain the enema more satisfactorily after the abolition of the spasm. The drug has been found to be of value also in the treatment of spastic conditions of the colon.

The dosage for the average patient is 30 mg. of benzedrine sulfate orally, very stout patients may require 40 mg., while thin and very young individuals are given from 10 to 20 mg. The patient ingests the opaque meal, and roentgenoscopic observations are carried out as usual. If there is spasm that does not disappear after manual pressure, reassurance and the other customary maneuvers, the benzedrine sulfate tablets are given with a few sips of water. After from

Fig. 6—The barium enema examination of the colon without the drug shows *A* a markedly spastic colon. The haustrations are deep and numerous. The caliber of the colon is very narrow. *B* after the administration of 30 mg. of benzedrine orally the haustrations diminish in number and depth. The colon is wider and distinctly less spastic than previously.

five to ten minutes the roentgenoscopic observations and taking of films are again carried out. The six hour, twenty-four hour or other desired observations are made as usual. In over 85 per cent of our cases, the drug has brought about satisfactory disappearance of the spastic manifestations. If the desired effect is not

obtained, we feel that it is preferable to repeat the examination with slightly greater dosage on a subsequent date rather than to give an additional dose. The effect begins in about ten minutes and reaches its height in from fifteen to thirty minutes, it lessens within an hour and gradually disappears.

Unpleasant effects may occur in a very small number of cases (about 2 per cent in our series) and consist of chilly sensations, flushing, diarrhea and general malaise. We have administered the drug to more than 200 patients and in only one instance was there a severe reaction. This patient had chills, nausea, collapse, restlessness and diarrhea, however, these symptoms did not occur until several hours after the drug was taken, and there is doubt in our minds as to whether the drug was responsible. There is a definite feeling of well being after the use of benzedrine sulfate; there may be sleeplessness or restlessness during the following night if the drug is administered late in the afternoon. The drug causes moderate rise in blood pressure (about 20 to 50 mg. of mercury) and we therefore recommend caution in its use in the presence of severe cardiac disease. On the whole we believe that the drug is nontoxic and in the doses recommended may be used

Fig. 7—The routine examination of the colon by opaque enema shows *A* a spastic contracted colon. *B* after the administration of benzedrine sulfate the colon is atonic with but few shallow haustrations.

safely wherever desired. In a series of several hundred patients given similar doses during the course of other investigations by Myerson and his co-workers, no ill effects were observed. There has been noted no idiosyncrasy to the drug in single doses except in some cases of mental disease.

SUMMARY

1 Benzedrine sulfate is a sympathicomimetic drug which has been found to be of great value in diminishing or abolishing spasm of the gastro-intestinal tract.

2 This effect is observed when the spasm is due to whatever cause, such as unpleasant emotion, organic disease of the gastro-intestinal tract, and reflex spasm due to disease elsewhere in the body.

3 This effect greatly facilitates the roentgen study of the gastro-intestinal tract, makes differential diagnosis between functional and organic spasm more certain, and gives better visualization of organic lesions.

4 The effect is almost immediate and is, on the whole, unattended with any side effects of importance.

5 Clinically it has been found useful in relaxing spasm, such as is found in spastic colitis and pyloric spasm, and this has been of therapeutic benefit to the patient.

THE STATE OF THE STERNAL
BONE MARROWIN A CASE OF MACROCYTIC (PERNICIOUS)
ANEMIA OF PREGNANCYNORMAN HEILBRUN, MD
BUFFALO

Normal hematopoiesis depends among other things on the formation of an antinutrient factor, which comes from the interaction of an intrinsic factor found in the gastric juice and an extrinsic factor present in the diet.¹ The antinutrient factor which produced is apparently stored in the liver.² If there is a lack of intrinsic factor or extrinsic factor or if there is disease of the liver so that the antinutrient factor is not stored, macrocytic anemia will develop.

The macrocytic anemia of sprue has been studied and the relationship between it and true pernicious anemia both from the point of view of a lack of essential factors and the similarity of the bone marrow in relapse has been emphasized.³ Clinical studies have shown that in the macrocytic anemia of pregnancy there is a temporary lack of the intrinsic or the extrinsic factor.⁴ This brings about a blood picture similar to true pernicious anemia which therapeutically responds to substances containing the antinutrient factor. Adequate reports of the condition of the marrow in macrocytic anemia of pregnancy are few and somewhat inconsistent, the cases reported were seen in India. One author states that the marrow is mostly aplastic but that megaloblastic cells are present.⁵ Another⁶ reports that the marrow is hyperplastic and that non-granular mononuclear cells and myelocytes are greatly in excess. No studies of the state of the marrow of cases seen in the Occident seem to have been described. The case given here presented the opportunity of studying the sternal marrow of a young American woman with this condition. Biopsies were obtained both before and thirty-one days after treatment with liver extract was started.

METHOD

A small incision was made in the sternum between the third and fifth costal cartilages. The periosteum was elevated and a small button of bone removed with a trephine. Smaller fragments were obtained by means of a small curet. The periosteum was next sutured with fine catgut, and the skin was approximated with horsehair sutures. A tight bandage was then applied. The button and larger fragments were used for sections. These were fixed in Zenker's fluid and 5 per cent acetic acid, decalcified, embedded in paraffin, sectioned, and stained with eosin-methylene blue and Giemsa stain. Smears, prepared from the smaller fragments, were stained with Giemsa stain.

REPORT OF CASE

A white woman, aged 21, married, admitted to the First Medical Service of the Buffalo General Hospital April 24, 1935, had been delivered of a normal female child three months previously. She complained that for the past month she had suffered a loss of appetite, which had been accompanied by more or less continuous nausea and vomiting during the two weeks prior to admission, and that slight exertion brought on severe dizziness with spots and blackness before the eyes, followed by marked prostration. Precordial pain on exertion had been present a week and swelling of the ankles was noted two days prior to her entrance. However, with difficulty she had been able to carry on her work up to the day before admission.

During the last month of her pregnancy her appetite had begun to fail and she had eaten little more than a small daily portion of fruit and vegetables with meat once or twice a week. After term her appetite did not improve and during the four months before admission she had lived largely on milk and a small amount of fruit with little or no meat.

On admission she was extremely sick. Pallor and dyspnea were marked. All the accessory muscles of respiration were used. The temperature was 100.5 F, the pulse 120 and the

Fig. 1—Section of sternal marrow removed at biopsy before treatment was started. Note the absence of fat and the presence of great numbers of megaloblasts with a reduction of the normoblastic and myelocytic elements. (Low power)

respirations 26 per minute. The pupils reacted to light and to accommodation. Small flame shaped hemorrhages were present in both fundi. The tongue was pale and smooth, but no glossitis was present. Dental caries was present. Percussion showed that the heart was slightly enlarged to the left. A loud, harsh, systolic murmur was heard over the precordium and most intensely over the second left interspace. The blood pressure was 90 systolic, 40 diastolic. The liver was moderately enlarged and tender. Pitting edema was noted over both lower extremities, but there were no pathologic neurologic manifestations. The blood count on admission showed 450,000 erythrocytes with hemoglobin of 15 per cent by the Newcomer method. Examination of the stained smear revealed a macrocytic type of anemia, characterized by large oval cells well filled with hemoglobin which was in no respect different from that seen in true pernicious anemia. There was a slight leukopenia, but no abnormal white cells were seen. The icteric index was 25, and the quantitative van den Bergh test showed 14 mg. of bilirubin per hundred cubic centimeters of blood. The blood urea nitrogen was 39 mg. per hundred cubic centimeters of blood. The total serum proteins were 4.5 per cent, the albumin 3.1 per cent, and globulin 1.4 per cent. This low level of the proteins no doubt accounted in part for the edema that was present. The urine was of normal concentration. It showed a slight trace of albumin and a sediment containing many pus cells.

Urobilinogen was present in a dilution of 1 to 40. Vomitus obtained on admission showed the presence of free hydrochloric acid and pepsin.

A transfusion with 500 cc. of blood was performed soon after admission and the following day a sternal biopsy was made. Large doses of liver extract were then given intramuscularly daily during the first week and once a week thereafter. Marked improvement was noted during the first few days, and the patient made a progressive recovery. The blood examinations are listed in the accompanying table. The temperature ranged from 99.5 to 102 F. for about three weeks and gradually fell to normal at the end of the sixth week. During the first week hoarseness was noted, and a laryngoscopic examination revealed a complete paralysis of the left vocal cord which, however, had almost disappeared by October. From the table it is seen that there was a prompt reticulocytic response to the liver extract, and the count showed a steady increase in the red blood cells and hemoglobin. It is interesting to note that about six weeks after treatment was started, the marrow began to change from the macrocytic type to the more common microcytic hypochromic variety, it is not unlikely that both conditions were present in this case at the beginning but that the iron deficiency did not become apparent until the count reached the higher levels. At the end of June the patient was put on ferrous sulfate which she continued until the first part of August when the number of red cells and the hemoglobin concentration were within normal limits. She was not seen again until October. The count then revealed that the hemoglobin had dropped in spite of the steady increase in the number and size of the red cells. Ferrous sulfate was started again.

BIOPSY BEFORE TREATMENT

The smear stained with Giemsa stain showed numerous megaloblasts. The hemoglobin in the cytoplasm varied from none at all to almost normal concentration. These cells comprised at least half of all the nucleated cells. Normoblasts and granular leukocytes were present. The granular cells consisted of neutrophilic myelocytes, young polymorphonuclear

blasts with dense small nuclei, which were oval, round or clover shaped. The cytoplasm of some of these was slightly more abundant than others. Some were deficient in hemoglobin and stained grayish blue or had small purplish granulations in the cytoplasm. Here and there were megakaryocytes, the nuclei of which had the same characteristics as the primitive cells. There were some small deeply stained naked nuclei, apparently

Fig. 3—Section of sternal marrow removed at biopsy thirty-one days after treatment was started. Note the large number of normoblasts, myelocytes and young polymorphonuclear cells. The megaloblasts are almost completely absent. (Low power.)

normoblastic in origin. Myelocytic elements were strikingly infrequent. The eosinophilic cells appeared to be slightly increased. Some had large oval nuclei and others the typical polynuclear lobulations. Histologically this was a distinctly abnormal marrow.

Blood Examinations

Fig. 2—Field from figure 1 under higher magnification. Note the large number of megaloblasts (round pale nuclei) almost in syncytial arrangement and the small number of normoblasts (round dense nuclei).

cells, and eosinophilic myelocytes and leukocytes. The latter seemed to be slightly increased in number. A few megakaryocytes were seen.

The section of marrow showed complete cellularity and an absence of fat. The microscopic appearance is illustrated in figures 1 and 2. Fully half the cells were large, with faintly staining nuclei and abundant pale blue cytoplasm. These were somewhat irregular in shape but the nuclei were round or slightly ovoid with one or two nucleoli. The cells seemed almost syncytial. There was a moderate number of normo-

BIOPSY THIRTY ONE DAYS AFTER TREATMENT

The stained smear was strikingly different from the previous one. Very few megaloblasts were seen. There were large numbers of normoblasts, many neutrophilic and eosinophilic myelocytes and many young neutrophilic leukocytes and eosinophils. These cells seemed to be in normal proportions. An occasional megakaryocyte was seen.

As in the first biopsy the marrow was completely cellular. The microscopic appearance is illustrated in figures 3 and 4. However, there was a very marked reduction in the number of immature red cells (megakaryoblasts), which were present only in small numbers in a few isolated areas. Some of these stained faintly pink. There were many more mature erythrocytes, and the number of normal nucleated red cells (normoblasts) was greater. The myelocytic elements were markedly increased above the number in the previous biopsy. There were many eosinophilic myelocytes and leukocytes and a great abundance of neutrophilic myelocytes and leukocytes. The megakaryocytes appeared to be about the same in number as before. The constituents were normal but the marrow was hyperplastic.

COMMENT

The material from the sternal marrow in this case indicates that in the macrocytic anemia of pregnancy the change is fundamentally the same as that in true pernicious anemia and in the macrocytic anemia of sprue.

During relapse, both in pernicious anemia and in sprue, the marrow is characterized by extensive cellularity, chiefly owing to megakaryoblastic proliferation with a diminution of normoblastic and myelocytic elements.⁷ On the administration of liver extract this megakaryoblastic proliferation ceases and the normoblastic and myelocytic cells return to their normal ratios. The changes are somewhat proportional to the degree of the anemia, i. e., the more severe the anemia the greater the megakaryoblastic hyperplasia. The sternal marrow in this case showed a similar megakaryoblastic hyperplasia with reduction in the normoblastic and granular elements and after therapy with liver extract showed a similar return to normal.

Strauss⁴ has pointed out that in the macrocytic anemia of pregnancy there is a failure in the formation

was found both in the vomitus and in the gastric juice. Wintrobe and Shumacker⁸ have recently suggested that the fetus in the development of its blood-forming tissues utilizes the antianemic factors elaborated by the mother. There is a definite macrocytosis of the red cells early in fetal life and as term is reached, the cells approach normal size. If the amount of antianemic factor formed is too small (owing to insufficient amounts of either intrinsic or extrinsic factors as shown by Strauss), and this is all utilized by the fetus, the maternal blood forming tissues are inadequately supplied. The soil for the development of macrocytic anemia in the pregnant mother is thus prepared.

CONCLUSION

The bone marrow in a case of severe macrocytic anemia of pregnancy was studied. It was found, first, that the bone marrow resembles that seen in true pernicious anemia and in the macrocytic anemia of sprue during relapse and, secondly, that under the influence of specific therapy the cell constituents return to normal, as has been found when pernicious anemia and the macrocytic anemia of sprue are treated in a similar manner.

Clinical Notes, Suggestions and New Instruments

PACHYONYCHIA CONGENITA

ELMORE B. TAUBER, M.D., LEON GOLDSMAN, M.D., AND
HARRY CLAASSEN, M.D., CINCINNATI

Pachyonychia congenita is a rare and uncommon condition. It is quite possible, however, that many cases are overlooked and they may be diagnosed as a simple congenital deformity of the nails. Most of the cases reported have been in children for the reason that this condition is a particular form of a congenital abnormality.

This particular syndrome includes more than deformities of the finger nails. The title of Jadassohn and Lewandowski's paper in 1906 'Keratosis Dissemuata Circumscripta Tylosmata and Keratosis Linguae' shows the essential features of this condition. Pachyonychia seems to be the constant symptom in all the cases reported. The others include bullae palmar and plantar keratoses, leukoplakia, anomalies of the hair, follicular keratoses of an acneform type especially on the knees and elbows, and dyskeratosis of the cornea. Heller¹ includes these changes under the term congenital dyskeratoses. Most of the cases seem to have been reported in males, chiefly Jews of Slavonic origin. Kumer and Loos² recently have studied a family of five generations and found thirty-four cases. From their cases and from a survey of the literature, they believe that pachyonychia congenita can be divided into three classes:

- 1 Type I Symmetrical keratoses of hands and feet with follicular keratoses of body.
- 2 Type II Symmetrical keratoses of hands and feet, follicular keratoses of body and leukokeratoses oris, this is the commonest type (typus Riehl).
- 3 Type III Symmetrical keratoses, follicular keratoses of the body and corneal changes.

The recent reports in the American literature of Diasio,³ Sohrweide⁴ and Andrews⁵ give excellent summaries of the

Fig. 4.—Field from figure 3 under higher magnification. Note the cluster of normoblasts just above the center. This is surrounded by myelocytes and young polymorphonuclear cells.

of antianemic factors similar to that in true pernicious anemia except that this failure is only temporary. This deficiency of antianemic factor may be the result of a lack either of the extrinsic factor in the diet or of the intrinsic factor in the gastric secretions. The diet in the case reported was deficient. Free hydrochloric acid

literature and add three new American cases. The case reported here combines all the features of pachyonychia congenita. This case was overlooked for a long time, being considered an atypical type of epidermolysis bullosa presenting nail deformities, chiefly because of the prominence of the bullae on the extremities.

REPORT OF CASE

The diagnosis in this case was made at the Mississippi Valley Central States Dermatological Conference in Cincinnati, Nov

ments, calcium and viosterol. The recent addition of the x-rays to the therapy, one erythema dose in divided doses, gave the patient great relief for a time.

Examination of the patient shows that she is well developed, of the brunette type. The skin in general, especially over the extremities, is dry and scaly. There is a mild papulopustular acne of the face. The finger nails show wrinkling and thickening and, for the most part, are deformed completely. The toe nails exhibit the same changes, perhaps a little more exaggerated. There is also a small amount of deformity visible on the great toe on the left. Scattered over the soles of both feet are large, oval, oozing areas covered with a red, smooth, moist base. These lesions have a foul odor. No inflammatory reaction has been noted about these lesions. There are similar lesions over both heels. On the lateral aspect of the right foot, and in the mesial aspect of the left foot, are thin bluish-like scars representing healed areas. Sweating of the hands and feet is present, though not marked. Dermoglyphism is not present. Nikolsky's sign, even on the plantar surfaces of the feet, is negative. The mouth is normal except for the tongue, which shows definite atrophy and whitish leukoplakial areas along the lateral portion. The buccal mucosa is normal. Palpation shows no thickening. Vaginal examination was not done. The remainder of the physical examination was negative. Repeated examinations were negative for fungi on the nails of the hands and feet. Smears of the oozing skin lesions show staphylococci.

Fig 1—Deformity of nails and thickening of derma

16, 1935. A Jewish girl, aged 20, had had since birth thickening and wrinkling of the nails of the hands and feet. Shortly after birth also some dryness of the skin was noted. In 1930, painful blisters appeared spontaneously over the soles of the feet and

Fig 2—Nails are deformed, thickened and wrinkled

about the toe nails. About this time also the patient complained of some slight burning of the tongue. No blisters appeared on any other surface of the body or about the hands at any time. In 1932 the large toe nail on the left foot was removed surgically. Since 1930 the lesions on the feet have shown some slight improvement. Some of the large bullae have healed completely. The therapy has consisted of various mild local oint-

Fig 3—Scars on side of right foot

The patient has been under observation for some time and the nails show no definite improvement, but there has been some spontaneous healing of many of the small bullous lesions about the toes and of several of the larger lesions on the plantar surfaces of the feet. The patient believes that she got the greatest relief from roentgen therapy. At the present time she is wearing a special shoe and a protective cotton boot.

COMMENT

This case then, showed pachyonychia palmar and plantar keratoses, mucous membrane changes, and a generalized degree of mild ichthyosis. Our patient was disturbed, outside of cosmetic disfigurement, by the presence of the large, painful bullae, which so frequently became secondarily infected. During the period of observation of the patient we could watch the spontaneous healing of some of the bullae. From the pathogenesis of this condition repeated trauma and friction seem to be a predisposing factor for the development of these bullae. With the institution of bed rest, elevation of the feet, and protection of the feet with cotton boots, and special shoes when walking the patient secures some relief. Because of the presence of areas of leukoplakia in her mouth the patient was cautioned about the importance of good dental care, the avoidance of tobacco and any irritating articles in her diet. In the reports in the literature, no cases of malignancy superimposed on this condition have as yet been described.

DIVERTICULUM OF THE PROSTATIC URETHRA WITH STONE

J. HAROLD CLARK, M.D., NEW YORK

Diverticula of the prostatic urethra, whether congenital or acquired, are exceedingly uncommon. A search of the literature reveals some half dozen cases that may be considered authentic.

A man aged 53, a plumber, seen in November 1932, had been suffering acutely for several days from an overdistended bladder from which the urine was being expelled in drops and with great difficulty.

Fig 1—Cystogram showing extravascular position of stone

The past history revealed nothing of interest to this report beyond a gonorrheal infection when he was about 20, which was followed by the characteristic story of stricture and periodic relief obtained by the ancient method of rapid expansion.

He was removed to the hospital, where gradual dilation of the strictured urethra was instituted and a physical examination

Fig 2—Cystogram and urethrogram showing diverticulum of prostatic urethra

revealed also an infected urine, a four plus Wassermann reaction and, according to the x-ray report, a stone in the bladder.

He was told on leaving the hospital that after the stricture had been sufficiently dilated and the syphilitic condition favorably influenced by treatment, the stone could be removed.

Since the patient was willing and cooperative, the treatment outlined was successfully carried out and in July 1934 a cystoscopic examination was made to check the roentgenographic observations. The examination showed a pale dull trabeculated bladder with two small apertures behind the right ureter mouth but no stone.

Fig 3—Urethroscope in prostatic urethra with catheter passed into cavity of diverticulum

A new set of stereoscopic roentgenograms was then made by another technician and the report was again made of stone in the bladder. Comparing these plates with the original pictures of one and one-half years before, nothing of interest was noted except the fact that the shadow had assumed a lengthwise instead of a transverse position.

Fig 4—Urethroscope in prostatic urethra with flexible forceps passed into cavity of diverticulum

After another negative check-up cystoscopy a number of cysto-urethrograms were made which clearly revealed not only a small vesical diverticulum but a large prostatic urethral diverticulum. This group demonstrated the fact that the stone shadow was extravascular.

A urethroscopy was then done, which showed with brilliant clarity the orifice of the prostatic urethral diverticulum. This opening was about one-fourth inch in diameter and to the left of the colliculus and in the middle of the lateral sulcus, about half an inch below the level of the utricle and ejaculatory ducts. It was a simple matter to pass a ureteral catheter into this pouch for a distance of an inch or more.

On a subsequent day the patient was prepared for operation. This was preceded by a preliminary urethroscopy and an attempt to pass a flexible forceps into the diverticulum on the chance of clicking against the stone and possibly grasping and withdrawing it, thus obviating an open operation. This not succeeding, the urethra was opened, under spinal anesthesia and with the finger the stone was easily milked out of the pouch and delivered. Digital examination revealed the diverticulum to be a patch pocket affair, which might easily have been removed had I not reasoned at the time that with restored urethral caliber and drainage this would be of no particular advantage.

The wound was healed and the patient was out of the hospital in a week, no better or worse than he was before, as neither the diverticulum nor the stone had ever given him any uneasiness.

The pathologist's report stated that the calculus was very hard, covered by a thin brown layer under which the center was chalky white. The outer layer was composed of cellular debris and urates. The core and main bulk were calcium carbonate with a little earthy phosphate.

As the pyuria did not entirely clear up during the succeeding two or three months I decided to obliterate the wall of the sac by fulguration. This was very simply carried out in two sittings.

This diverticulum seemed clearly to be of the acquired type and it was occasioned by the urinary back pressure brought on by a distal urethral stricture. It seems probable also that the opening of a prostatic duct was the starting point of the diverticulum.

ELIMINATION OF CONFUSING GAS SHADOWS DURING CHOLECYSTOGRAPHY BY THE USE OF PITRESSIN

E. N. COLLINS, M.D. AND J. C. ROOT, M.D., CLEVELAND

The recent publication by K. I. Melville¹ on the 'Pressor and Oxytocic Fraction of Posterior Pituitary Extract' prompts this preliminary report of our experience with the use of the

pressor fraction of posterior pituitary extract (pitressin) in selected patients having cholecystographic examinations. In the course of 600 cholecystographic examinations the use of this preparation was deemed advisable in seventy-three instances.

Confusing densities in the right side of the abdomen, usually in the intestinal tract constitute one of the most common handicaps to the accurate interpretation of cholecystograms even though cleansing enemas are used as routine procedures. Not uncommonly more gas is found in the intestinal tract after enemas have been used than was present before their administration.

Fig. 1—Cholecystogram made fourteen hours after oral administration of 5 Gm of sodium tetraiodophenolphthalein.

We have found the use of pitressin more effective than the use of enemas. It is a simpler procedure, requires less time, is less troublesome to the patient, particularly if not in a hospital

and has not been attended by any unpleasant reactions. It has precluded the necessity for reexaminations in numerous instances.

METHOD

Details of our routine cholecystographic examinations have been published elsewhere.² The single dose oral method is used, but in those instances in which nonvisualization occurs, a second dose of the dye has been given the second night even though studies of the stomach and small intestine following a barium sulfate meal have been made in the meantime. In the absence of cardiovascular contraindications we now use one ampule (10 pressor units) of pitressin as a routine in cases in which confusing shadows in the right side of the abdomen interfere with the accurate interpretation of the cholecystograms. Additional cholecystograms are made from forty-five to sixty minutes after the injection of the drug. The increased tone of the intestinal tract after the administration of pitressin has permitted accurate study of the gallbladder area even though the colon contains barium sulfate. There has been no apparent interference with roentgen studies of the stomach and duodenum in which the barium sulfate meal is used or in examinations of the colon in which the barium sulfate enema is used on the same day on which pitressin is used. This preparation has not been used in patients having a systolic blood pressure below 100 mm of mercury or in patients who have advanced hypertension or suspected coronary disease.

Fig. 2—Cholecystogram made on same patient forty-five minutes after the intramuscular injection of pitressin.

RESULTS

Effective results were obtained in 82 per cent of the seventy-three cases (figs. 1 and 2). 75 per cent of these patients had one or more stools within thirty to forty-five minutes after the intramuscular (deltoid) injections of one ampule (10 pressor units) of pitressin. In practically all instances in which it was used, intestinal activity was evidenced by mild cramplike sensations in the abdomen together with a feeling of expected defecation if this did not actually occur.

No change in either the systolic or the diastolic blood pressure was encountered in 9 per cent of this series of seventy-three cases. In approximately 50 per cent there was a drop in blood pressure. A drop in both systolic and diastolic pressure occurred in 35 per cent, lowered systolic with no change in the diastolic in 7 per cent, lowered diastolic with no change in the systolic in 5 per cent. The average drop in systolic pressure was 15 mm of mercury and the average drop in the diastolic pressure was 14 mm of mercury.

In 36 per cent of the seventy-three cases there was an increase in blood pressure. This increase occurred in both systolic and diastolic pressure in 17 per cent, in systolic with no change in the diastolic pressure in 16 per cent, and in systolic with lowered diastolic pressure in 2 per cent. The average rise in systolic pressure was 10 mm of mercury and the average rise in diastolic pressure was 10 mm of mercury.

In those instances in which the blood pressure was taken every five minutes for one hour, there was a gradual and progressive fall in both the systolic and the diastolic blood pressure during the first thirty or forty minutes and then a gradual and progressive rise in both until the end of the hour, but in no instance was the terminal reading as high as that before the administration of pitressin.

From the Cleveland Clinic.

THE TREATMENT OF A LUNG ABSCESS DUE TO
BACILLUS COLI WITH A LYTIC FILTRATESAMUEL MORRISON M.D. AND RAYMOND E. GARDNER Sc.D.
BALTIMORE

Numerous reports on bacteriophage therapy in human infections have been made with some apparently favorable and some poor results. A critical review of this form of therapy has been published by Eaton and Bayne Jones¹ who call attention to the more plausible and possible means of application of the lytic principle *in vivo*. This review indicates from the experimental and scientific points of view those cases in which such therapy is at least warranted. Eaton and Bayne Jones called attention to the specificity of the agent for the organism producing the pathologic condition, the inhibitory action of body fluids, the species susceptibility of the organism in *in vivo* experimental infections, and the mode of application. They also state that it is not certain whether the bacteriophage itself or other constituents of the lytic filtrates produce the effects observed," when an improvement in a disease process is noticed.

In the following case² is a measure of last resort bacteriophage therapy was tried, particularly since the conditions for its application were apparently suitable.

N. S., a woman, aged 22 who had previously been in excellent health suddenly experienced a severe diffuse abdominal pain Aug. 5, 1934 which was mistaken for menstrual cramps. During the following two days enemas were given but with no relief. On the third day the patient's condition became critical and she was rushed to the Chambersburg (Pa.) Hospital where an emergency operation was performed by Dr. L. H. Seaton. When the abdomen was opened a gangrenous appendix with generalized peritonitis was disclosed. The remainder of the appendix was removed and drains were inserted. The postoperative course was stormy and the patient's condition was indeed grave. The temperature was hectic ranging from 98 to 105 F with intermittent chills. Owing to the general peritonitis, hot packs were used to localize the inflammatory changes in the lower right quadrant. These hot packs were used continuously for six weeks along with daily saline irrigations through the midline incision. Thick purulent contents were obtained throughout this period.

August 29 the patient complained of a sudden severe pain under the left shoulder blade, which was first interpreted as pleurisy, and the clinical signs were those of pleurisy. There were no signs of an infection of the upper respiratory tract such as a sore throat or the ordinary common cold. The patient's chest was strapped with resulting temporary relief. For one week after the strapping the pain was usually dull but there were occasional mild exacerbations. However, at one time after an excruciating pain, examination disclosed massive collapse of the left lung. During the subsequent few days slight signs of partial return of pulmonary function were observed, but relapse followed. Clinical and x-ray signs of effusion developed. Aspiration was performed September 12 and 500 cc of very heavy purulent material with a foul and typical colon odor was obtained. A culture of the pus at this time yielded only *Bacillus coli*. Three days later because the material was too thick to be aspirated, rib resection was done with a virtual gush of pus. A bronchial fistula developed shortly after the rib resection and the patient was expectorating the same kind of material as that which drained from the resection wound. The appearance of the area around the resection opening was necrotic and 'mossy' and failed to show any improvement on local irrigations with 1000 cc of saline solution twice a day. Digital examination through the resection wound disclosed many walled off abscesses surrounded by necrotic tissue. In view of the hectic fever and the general condition, which indicated toxic absorption, an especially resistant abscess which failed to open was incised by an approach between the ribs just above the rib resection. A drain was inserted and in a few days healing took place.

Since the appearance of the resection wound showed advancing necrosis and continued drainage of from 1 to 2 liters of pus seemed to add to the rapidity of necrosis the outlook was altogether discouraging. At this time (September 16) we learned of the patient's condition and obtained Dr. Seaton's ready permission to try bacteriophage therapy. The decision to use bacteriophage was made for the following reasons: 1. The apparent invader was a colon bacillus. 2. One of us had at hand a polyvalent colon lytic filtrate which could be tested for specificity and potency. 3. The site of invasion was local and inhibitory body fluids could be diluted by salt irrigation even though pus supposedly has little action on colon bacillus bacteriophage.³ 4. The type of pathologic condition presented a means whereby concentrated bacteriophage could be returned in the chest and wet dressings of bacteriophage applied to the necrotic resection wound.

A second sample of pus was collected at this time (September 16) and another pure culture of colon bacillus isolated which was fairly readily lysed by a bacteriophage that was active against various strains of *B. coli* isolated from other sources. Within two days the activity of the bacteriophage was increased to a titer of 1 to 200,000,000 against the specific organism completely sterilizing young cloudy broth cultures within two hours.

After a cutaneous test September 20 of 0.1 cc of the lytic filtrate twelve hours previously had given little or no reaction and after irrigating the chest with 1 liter of physiologic solution of sodium chloride, 1 ounce (30 cc) of the phage was instilled and allowed to remain for two hours. This was followed by saline irrigation and the wound covered by a dressing saturated with the bacteriophage. The following day the observation was made that the discharge had become thin and watery and had lost its offensive character for the first time since the resection was done five days before even though saline irrigations had been administered twice daily during this five day period. A second and equally remarkable change had occurred at the resection wound itself, where the mossy necrotic character was entirely changed to a clean, fresh healthy appearing incision. Since the first use of bacteriophage had given such excellent results a second application seemed indicated and therefore the procedure was repeated. However, within ten minutes a violent generalized rose-colored urticaria appeared and the patient complained of nausea and vomited. The bacteriophage was drained immediately and the chest irrigated with large quantities of saline solution. Epinephrine was administered and the eruption cleared within an hour. The patient, among others known to one of the authors reacted to the epinephrine with a thready pulse and cold and clammy skin. The epinephrine reaction however completely subsided in the course of another hour. After such a marked allergic reaction to the bacteriophage had occurred it was decided to discontinue bacteriophage instillations and continue only with saline irrigations and external dressings saturated with bacteriophage. The dressings of bacteriophage were continued for a week along with irrigations of physiologic solution of sodium chloride. Throughout this period the resection wound maintained its healthy normal appearance and the discharge remained clear watery and non-odorous. The temperature reached 102.2 F each day for the thirteen days prior to the urticarial reaction. On that day the reading was 103.2 F after the reaction. After this reaction the temperature did not go above 102.2 F.

The patient's general condition was remarkably improved and within six weeks she was able to leave the hospital. The appendiceal wound had healed but the fever, less hectic in type continued as well as the thin nonodorous drainage. At home the fever gradually subsided as well as the drainage, and healing was practically complete toward the end of December.

At the present time the patient has regained her weight (65 to 120 pounds or 29.5 to 54.4 Kg) and is perfectly healthy and has resumed her occupation. Interestingly enough, the loss of hair that had occurred during the continued and prolonged febrile illness has entirely regenerated.

SUMMARY

A ruptured appendix with peritonitis was followed by an infected embolus, which produced a massive collapse of the

¹ Eaton M. D. and Bayne Jones Stanhope. Bacteriophage Therapy. Review of the Principles and Results of the Use of Bacteriophage in the Treatment of Infections. *J. A. M. A.* 103: 1769 (Dec. 8) 1934; (Dec. 15) (Dec. 22) 1934.

² We are indebted to Dr. L. H. Seaton Chambersburg Pa. for allowing us to report this case.

³ Appelbaum Martha and MacNeal W. J. Influence of Blood and Exudates on the Action of Bacteriophage Against Colon Bacillus. *J. Infect. Dis.* 50: 269-276 (March) 1932.

left lung, followed by empyema, all resulting from the colon bacillus. The patient's life was despaired of and it was agreed to use any measure that might offer some hope. Bacteriophage therapy was resorted to, especially since the conditions for its application seemed suitable. The procedure adopted apparently played an important role in the patient's recovery because of her immediate change after the application of the filtrate, whereas surgical measures promoting drainage as well as repeated irrigations with physiologic solution of sodium chloride, did not seem to control the necrosis and suppuration in the chest. Whether the bacteriophage acted as a specific or indirectly as a synergist to antibody formation cannot be stated. In addition, the progression of the infectious process gave no time for trial and error methods with plain broths, since we had at hand a liter of extremely potent specific lytic filtrate.

If any conclusions can be drawn, the rapidity of clearing (twenty-four hours) in a chronic process would seem to suggest specifically rather than marked antibody formation.

Special Clinical Article

TREATMENT OF ATROPHIC ARTHRITIS

CLINICAL LECTURE AT KANSAS CITY SESSION

W PAUL HOLBROOK, M.D.

AND
DONALD F HILL, M.D.

TUCSON, ARIZ

Atrophic arthritis is a constitutional disease which manifests itself as a profound systemic disturbance and by a chronic deforming polyarthritis. It should be clearly understood in the beginning that atrophic arthritis is a disease without a known single specific etiologic agent and likewise there is no single specific cure. In a previous paper one of us¹ reported carefully controlled experiments with various types of therapy. This consisted of placing a large group of patients with atrophic arthritis on a general program which included dietary correction, bowel management, prevention and correction of deformity rest, exercise, general physical therapy and climatic residence. After a control period of several months one group had foci of infection removed, another group was given blood transfusions, the third group was given vaccine of various types, and the remainder were given special forms of heliotherapy. Progress was observed over periods ranging from months to years. The results of this study emphasized the nonspecificity of any single therapeutic agent used and the necessity of using a comprehensive program of management. Because of this lack of a specific cure the medical profession, much like the Children of Israel, is prone to wander after strange gods and attempt first one form of treatment and then another in the hope of finding an easy and miraculous remedy. While it is true that no specific and certain cure is yet available for this unhappy disease, enough is now known regarding its manifestations and treatment to prevent most of the deformities and to restore a large majority of these patients to useful lives.

There are undoubtedly multiple factors involved in the etiology of atrophic arthritis. Heredity, infection, climate, body types, fatigue, trauma, exposure, nervous

strain, circulatory disturbance, gastro-intestinal dysfunction, endocrine disorders, and no doubt many other factors play some role as etiologic agents. It is because of the many sided constitutional manifestations of this chronic disease that treatment, to be effective, in our present state of knowledge must depend not on one single agent but on a combined program of treatment in which every available therapeutic aid is utilized.

It should be remembered that atrophic arthritis may be initiated with all the acuteness of rheumatic fever, or it may begin most insidiously with very few symptoms. The disease may progress rapidly to crippling deformity or progress but slowly with little change from year to year. Because of these wide variations in onset and course, therapeutic measures must be selected for each individual and in relation to the acuteness of the disease. To simplify the beginning of treatment, we have adopted the plan of treating each new patient as an acute case and then, under observation as rapidly as possible advance him to the degree of activity for which he is ready. Before discussing the various therapeutic aids in detail, we present a case history illustrating the therapeutic procedures used in the different phases of the disease.

REPORT OF CASE

An unmarried woman, aged 36, presented as the chief complaints (1) pain, swelling, deformity and limitation of motion in both hands, wrists, elbows, shoulders, knees, ankles and feet of two years duration, (2) belching, nausea and pain in the right upper quadrant, (3) weight loss of 29 pounds (13 Kg) during the past year.

The positive conditions found on physical examination were (1) malnutrition (weight 81 pounds, or 36.7 Kg), (2) anemia, (3) fever of 99.5 to 100.5 F daily, (4) persistent tenderness over the gallbladder area, (5) both shoulders painful and motion limited to 50 per cent, both elbows were flexed and extremely painful, both hips showed a flexion contraction with extension limited to 140 degrees, the knees were hot and swollen, with extension limited to 145 degrees, the ankles and feet were swollen painful and useless.

Laboratory examination revealed 4,100,000 red blood corpuscles, hemoglobin 10.9 Gm, 79 per cent (Sahli), white blood corpuscles 6,500, sedimentation of red blood corpuscles 116 mm in one hour (Westergren). Stomach analysis revealed no free hydrochloric acid. Gallbladder drainage was four plus pus. Culture from the results of drainage showed a green producing streptococcus and enterococcus.

Röntgen examination revealed marked demineralization of the bones in the hands compared with a normal hand. Both knees showed increased density of soft tissue but there was no demonstrable erosion of cartilage. The gallbladder failed to fill with dye.

Treatment in the acute phase consisted of

- 1 Bed rest
- 2 A semibland, high vitamin and high calory diet with no limitation of starches
- 3 Dilute hydrochloric acid with meals
- 4 Tincture of belladonna to tolerance, three times daily before meals
- 5 Hot wet packs to the abdomen after meals
- 6 Bowel regulation without cathartics
- 7 Gallbladder drainage once weekly
- 8 A firm, non-sag bed
- 9 Plaster shells to both legs as posterior splints
- 10 Cockup splints for the wrists
- 11 Corrective exercises. Every joint was assisted through its full range of painless motion daily. Gradually decrease of assistive work and increase of active exercises were carried out.
- 12 Acetylsalicylic acid for relief of pain.
- 13 Transfusions, three of 250 cc each one week apart
- 14 Minute doses of vaccine subcutaneously at weekly intervals (autogenous from gallbladder and strongly skin positive)
- 15 General climatic advantage and air baths. No direct sun.

Read in the General Scientific Meetings at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 11, 1936.

¹ Holbrook, W. P. Evaluation of Therapy in Chronic Atrophic Arthritis. *Ann. Int. Med.* 7: 457 (Oct.) 1933.

At the end of four months the patient had gained only 10 pounds (4.5 Kg). The hemoglobin was up however from 79 to 97 and the acute phase had partially subsided. Flexion contractions of the hips and knees were only partially corrected and severe pain was continuing. The following routine was then carried out:

- 1 Under general anesthesia both hips and both knees were manipulated and completely straightened.

- 2 Plaster casts were applied to both legs and allowed to remain in place for one week. Casts were then removed and used as posterior shells.

- 3 Corrective and assistive exercises of the legs were re-instituted. Emphasis was placed on the extensor groups and on foot exercises.

- 4 Light massage was started and heat was applied to the muscles as tolerated.

- 5 Heliotherapy, local and general was given.

At the end of ten months the patient had gained 20 pounds (9 Kg) and no longer had fever. The blood count was normal. The hips and knees were perfectly straight and not painful or swollen. Muscle tone was excellent from bed exercises. The patient was able to move about on the bed moving all the joints freely without pain. The following routine was then begun:

- 1 The patient was allowed to stand on her feet with (a) corrective shoes with supports, (b) ice bandages to the knees and (c) properly fitted crutches.

- 2 The patient was instructed in correct posture and the use of crutches as walking was begun.

- 3 All corrective exercises were increased and a gradual increase in walking was permitted.

- 4 The diet was changed to a high vitamin diet, with limitation of concentrated starches.

The patient has been walking for nine months with no recurrence of knee or hip pain. There is no residual swelling or deformity. In the course of her management the patient became free from gallbladder symptoms and the laboratory and x-ray examinations showed a return to normal conditions.

THERAPEUTIC PROCEDURES

General—From the case history it will be seen that the treatment of atrophic arthritis can be clearly divided into two parts, constitutional and local. Every effort should be made by any and all proved methods to correct the constitutional factors and thus arrest the progress of the disease. The local treatment of the joints consists of prevention and correction of deformity with maintenance of muscle tone during the entire period of the disease so that no matter how long the disease may remain active the patient will retain the maximum joint motion with the minimum deformity.

No attempt will be made to review the literature on therapeutic procedures, as this has recently been done most completely by Hench, Bauer and their co-workers.²

Diet and Nutrition—Nearly every type of diet has been tried in atrophic arthritis. It is our experience that the patient does best on that diet which would be selected for him if he had no arthritis. If the patient is underweight, a full high calory high vitamin diet with no limitation of starches is given. A bland, semi-bland or high roughage diet is used, according to the patient's individual needs. Obese patients are given low starch and low fat diets for reduction of weight. In short, the patient's general condition should be considered, his gastro-intestinal tract studied, and a suitable diet prescribed. When the patient has gained adequate weight we then usually order for him a high vitamin weight maintaining diet, low in concentrated starches. This is done not because the starch is harm-

ful but because bread, potato and pastry eaters will seldom eat enough food containing adequate vitamins and minerals.

Bowel Management—Many patients with chronic arthritis worry constantly regarding toxic poisoning from the colon. Physicians in this country in particular have seized on the toxic colon as a ready explanation for the persistent arthritis after the patient has been relieved of all surgically removable organs. It is true that the colon may be the seat of chronic infection, but there is little justification for the many appliances, irrigations and antiseptics used in the colon to combat "toxic poisoning." Adequate intestinal elimination is important and should be secured without the use of drastic cathartics. A simple lubricant, proper diet, abdominal exercises, massage and habit time are usually sufficient. Tincture of belladonna and hot wet packs to the abdomen after meals are also of much help in selected cases. Local conditions such as rectal spasm, fissure and hemorrhoids should of course, be corrected.

Removal of Foci of Infection—If removal of foci is to be of value in the treatment of this disease it should be accomplished early. It is during this phase, however, that the procedure may be most hazardous. Many patients who are undernourished, anemic and fatigued experience an acute exacerbation and spread of the disease following removal of foci. In our experience this has been particularly true of infected tonsils. When infected teeth or tonsils are removed, the infection itself is not removed at once but more rapidly invades the surrounding tissue for a time thus giving the patient a sudden overload of infection. Every attempt should be made to raise the patient's level of resistance before submitting him to the shock of a surgical procedure and an overload of infection as well. We frequently precede such operations with a blood transfusion and, if it is feasible, a period of weight gain and rest. In far advanced arthritis of long duration with joint destruction foci should be removed only because of general considerations and not with the hope of arresting the disease. Finally, the removal of foci of infection will benefit but few patients unless it is carried out only as a part of a comprehensive plan of management.

Vaccines—No single phase of treatment is more controversial than the use of vaccine in atrophic arthritis. Scarcely a year goes by that some new vaccine does not make its appearance. Autogenous and stock vaccines, usually made from some particular strain of the streptococcus, are advocated by the majority of workers using vaccine. However, there is no unanimity of opinion among users of vaccine regarding the particular strain of streptococcus used or the preparation and administration of the antigen. In previous papers we³ have described a series of patients on vaccine therapy compared with control groups. Our results failed to show any better results in the group receiving vaccine than in the groups not receiving it. In spite of this unconvincing evidence in its favor, we have continued to use autogenous vaccines showing skin positive reactions in a small percentage of our patients. The vaccine is given in minute doses intravenously or subcutaneously. We believe but cannot prove that some patients are benefited, at least psychically, by its use. Until some organism is proved to be the specific etiologic agent for atrophic arthritis, it is not surprising

2 Hench, P. S., Bauer, Walter, Fletcher, A. A., Christ, David, Hall, Francis and White, Preston. The Present Status of the Problem of Rheumatism. A Review of Recent American and English Literature on Rheumatism and Arthritis. Ann. Int. Med. 8: 1315 (April) 1935 (May) 1673 (June) 1935. B 883 (Jan) 1936.

that stock vaccines prepared from a great variety of bacteria have failed to show specific results in treatment. We continue to condemn the indiscriminate use of vaccine and its use as a specific as this results in neglect of the basic constitutional management so essential in the treatment of every patient with atrophic arthritis.

Transfusions—We have given a large number of blood transfusions to patients with atrophic arthritis. The first two transfusions are usually given one week apart. At the end of a month if improvement has not been definite, additional transfusions are given. Patients with relatively acute or subacute arthritis respond well and often dramatically. The appetite improves, the red blood count and hemoglobin rise, the low grade fever usually disappears and joint swellings diminish. The very chronic disease with far advanced joint destruction may be somewhat improved symptomatically but no striking results are seen in this group. In using several donors on the same patient we have often observed that the blood from one donor would regularly produce a better response than the blood from the other donors. Further study in the selection of donors is indicated. Blood transfusions are in no sense a specific cure but in our experience they have been an extremely valuable adjunct in building up the patient and arresting the disease.

Medicines—Acetylsalicylic acid for the control of pain, iron in correcting anemia and arsenic (as solution of potassium arsenite or neoarsphenamine) have a rightful place in the list of medicines used.

Sulfur injections and the use of gold salts have been disappointing in our experience.

Dilute hydrochloric acid provides better digestion and nutrition in the patient with low or absent gastric acid.

Vitamin A in the form of cod liver oil is given almost as a routine.

Many forms of vitamin B are available and we usually prescribe it in the form of wheat germ or yeast.

We have given crystalline vitamin C intravenously in 150 mg doses three times weekly to a small group of patients over a period of several months without observing any striking benefit.

A series of twenty-five patients in various stages of atrophic arthritis were given concentrated vitamin D in doses of from 200,000 to 350,000 units daily. All these patients had a control period of treatment of several months before beginning the vitamin D. This has been administered now over a period of four months. Five patients have reported less pain and four have had marked drops in their sedimentation rate. Sufficient time has not elapsed to evaluate this method of therapy.

Fever Therapy—In the treatment of atrophic arthritis, fever therapy has been disappointing. In a series of fifty patients who were given fever treatments, no patient was rendered symptom free. These patients received from four to seven treatments each and the temperature was maintained above 104 F for five or six hours. Approximately 25 per cent of these patients were temporarily improved. This is in accord with the recent reports from other workers.

Foreign Protein Injections—Injections of typhoid vaccine intravenously and various nonspecific proteins have been used for a number of years in the treatment of arthritis. We have discontinued all such injections, particularly the protein shock therapy, except in the

occasional young well nourished individual whose disease is not acute. We have seen a number of patients who have had a rapid spread of the disease following this type of therapy.

General Physical Therapy—There is at present a widespread belief that a department of physical therapy must be equipped with several kinds of lights, bakers, a variety of electrical appliances, paraffin baths, and other appliances. It is true that most of this apparatus can be used with some benefit to the patient psychologically and physically. However, 85 per cent of our physical therapy requires only a thoroughly trained personnel. Postural correction, assistive exercises, and the teaching of corrective exercises constitute the major work in the physical therapy of atrophic arthritis. All this can be done with no apparatus at all. Motion should be limited to within the painless arc but pushed to the limit with some assistance. All exercises must be done slowly and exactly with a rest interval. The maintenance of muscle tone and of maximum joint motion depends on wisely directed exercise daily. Massage and heat is a much abused procedure. If used vigorously in the early stages of the disease, increased pain and soreness will result. If used wisely over muscles in the more chronic phase, it relieves muscle spasm and increases circulation. Active exercises of muscle groups are much more effectual and as soon as the patient is able replaces massage. No attempt will be made to discuss the various mechanical and electrical appliances used in the physical therapy of atrophic arthritis, as they are too numerous. Finally, it should be emphasized again that joint motion and muscle tone can best be secured by teaching the patient to help himself.

Prevention and Correction of Deformity—Flexion contractions and deformities that occur in this disease are making thousands of invalids yearly. In every patient with atrophic arthritis the possibility of residual deformity in all involved joints should be anticipated and prevented. If flexion contractions are present, they should be corrected at the earliest possible moment. The prevention of such deformities may be accomplished quite easily but their correction is more difficult. The deformities usually occur in flexion, particularly in the knees, hips, elbows, wrists and hands. Unfortunately, the patient develops the worst possible bodily posture. He lies in a bed that sags, and he places pillows under his knees and head. The hands, wrists and elbows lie flexed across the body. Such flexion deformities are increased if walking is allowed with bent knees or hips.

The patient should be at rest on a bed that does not sag. During the day he must spend several periods in bed without pillows and with all joints fully extended. If pain and muscle spasm interfere, plaster shells or posterior splints for the legs should be used. All painful joints should be splinted so far as is possible in extension. Group muscle exercises of the extensors should be given. Chest, abdominal and postural exercises must be stressed and practiced daily. Every joint must be moved through its full range of painless motion at least once daily. It is entirely possible in the treatment of this disease for the patient to attain the muscular development of an athlete by bed exercises alone. It is essential that posture be correct, knees straight and sufficient muscle strength be developed before the patient is allowed to begin walking. Correctly fitted shoes with good arch supports are an

dages to the knees, and a pair of crutches properly used will often make walking a painless and useful exercise instead of torture. The advice so often given to patients with bent and painful knees to keep walking no matter how much it hurts is the shortest route to the wheel chair. It is especially important that no weight be borne on a bent or painful knee. This only results in further damage to inflamed joint structures and is often the cause of irreparable damage. If flexion contractions of the knees or hips are present, a series of plaster shells will often provide sufficient relaxation to secure a correction of the deformity. Failure to secure complete correction may be due to an adherent capsule or adhesions. If by the use of posterior splints (relaxation casts) and physical therapy the knees are not promptly straightened in one or two months further measures are essential and the following procedure is carried out. With the patient under deep anesthesia to avoid voluntary muscle spasm the joints are carefully manipulated and the deformities corrected. Occasionally more than one manipulation is necessary for complete correction. The technic of the manipulation will not be discussed at this time. Plaster casts are applied and allowed to remain approximately one week, at which time the cast is spread and the leg taken out for assistive exercises. The casts are then used as posterior splints. Within a few weeks after straightening the legs we have been astounded to find a foot or knee that had been cold, clammy and swollen with the swelling gone and the extremity quite warm. In flexion contractions of the knee, manipulation alone cannot always be done safely to secure a full correction of the deformity. In such cases posterior capsular adhesions are usually present or there is marked shortening of the ligaments and fascia. A posterior capsulotomy⁴ by the Wilson method is done immediately if the manipulation fails and while the patient is still under anesthesia. The treatment following capsulotomy is identical to that following manipulation and does not delay the postoperative assistive exercises. It has been the general impression that manipulation of joints should under no circumstances be attempted during the active phase of the disease. However, many of these patients are in an active phase of the disease for months or years. It is true that the patient should first be improved constitutionally if possible, but recent experience has convinced us that the hazard of waiting longer than a few weeks or months is far greater than the hazard of straightening a joint in any stage of activity.

During the past two years we have done fifty-seven such manipulations of the large joints after careful control periods of treatment. We shall report on nineteen of these patients because they were under observation for from six months to seven years and had been refractory to all conservative attempts to correct their deformities. All had flexion contractions of the knees or knees and hips and were unable to walk. This group seemed destined to remain hopeless cripples. Seventeen of the nineteen patients improved from the standpoint of pain, swelling and circulation. Fourteen of the nineteen patients are now walking with straight legs. Three have straight legs but are not yet far enough advanced in muscle training to begin walking. Two have shown no marked improvement and probably will never walk, owing to far advanced joint destruction. The average duration of the flexion contractions was two and one-

half years. The oldest flexion contraction was in a woman, aged 65, who had had hip and knee flexion contraction of seven years' duration with considerable cartilage destruction in both knees and hips. She is now able to walk with crutches. Posterior capsulotomy was necessary in six of the knees manipulated to complete the straightening procedure. When capsulotomy is done, manipulation should be done with it to correct subluxation and restore full extension. Most knees, following correction of flexion contractions maintain motion and rapidly develop muscle tone. Occasionally one tends to become fixed in extension and then several subsequent anesthetics may be necessary to restore flexion. The hip flexion contractures are more difficult to correct and maintain because of a marked associated lumbar lordosis. Usually a few months on a hard bed after the manipulation will prevent the return of this disability when walking is begun. Many of the other joints, particularly the shoulders and feet, may be mobilized by careful manipulation.

Correction of joint deformity by manipulation is in no sense a cure for arthritis but wisely combined with a comprehensive program of treatment it is invaluable in relief of pain, increase in circulation, and in returning many bed invalids to useful lives. Manipulation of the joints should not be attempted unless one is prepared to give a full program of carefully supervised follow-up treatment over a period of months.

There are undoubtedly hazards in this procedure, such as fracturing demineralized bones, rupturing ligaments, damage to cartilage and injury to blood vessels. If the manipulation is carried out carefully, it is our belief that it can be done with relative safety, as we have had no complications in the group we have treated. Finally it is essential to emphasize that flexion deformity should be corrected early, beginning with the easiest and simplest method but progressing rapidly to whatever measure is necessary to effect a correction of the deformity.

Climate—We have observed a large number of patients with atrophic arthritis during their residence on the Tucson desert. Acute exacerbations of the disease are exceedingly rare. The incidence of atrophic arthritis among native whites and Indians is extremely low. Rheumatic fever is a medical curiosity. A large group of children have been sent to the Tucson desert because of recurrent rheumatic fever. Of this group not a single child has had a frank recrudescence of the disease during the past eight years of observation. Activity of rheumatic fever has been evaluated by means of fever, white count sedimentation of the red cells, electrocardiogram and clinical observation. Again it must be said that ideal climate is not a panacea for atrophic arthritis, but when utilized as a part of the constitutional management there is little doubt that it influences the disease favorably.

COMMENT

We believe that the successful treatment of these patients with atrophic arthritis is more satisfactorily carried out in a warm, dry climate. Most of our patients have traveled long distances for climatic change and are at least in some measure prepared financially to provide themselves with adequate care. We also are aware that thousands of patients not only cannot afford climatic change but cannot provide adequate medical and nursing care at home. For this underprivileged group, the establishment of hospitals and teaching cen-

⁴ We are indebted to Dr. J. B. Littlefield of Tucson for his cooperation in doing the capsulotomies reported in this paper.

ters devoted to the care of arthritis, much as it has been done for tuberculosis, appears to be the only solution. A survey of the state of Massachusetts recently revealed that there were more people suffering from chronic rheumatism than from tuberculosis, heart disease and cancer combined. Tuberculosis, cancer and heart disease may cause death, but unchecked arthritis leaves its victims a lifetime of crippling deformity. Almost every state and county has special institutions for the treatment of tuberculosis, yet not a single state or county in this country has such a hospital for arthritis.

Finally, a specific cure for atrophic arthritis is not yet available. It is not our intention to sound a pessimistic note, for we have every reason to be most optimistic regarding the results to be secured when adequate treatment can be obtained. We do believe, however, that it is time for the medical profession as well as the victims of this disease to recognize that there is no easy way. The wasting of time and money on measures of doubtful value should be stopped and all time and attention centered on the few simple measures of proved worth. A striking advance in the therapy of this disease can occur if physicians will stop treating these patients half-heartedly with each new remedy as it appears and frankly tell their patients what the problem of adequate treatment includes.

SUMMARY

Atrophic arthritis is a disease without a known single specific etiologic agent and likewise there is no single specific cure. Being such, and admittedly a constitutional disease, emphasis is placed on the necessity of a comprehensive program of treatment, utilizing accepted methods to correct all factors at fault and to build up the patient's general condition to arrest the disease.

Of equal importance is the prevention and correction of deformities. With proper and continuous care from the onset of the disease there should be very few deformities requiring special treatment.

Nineteen patients with flexion contractions of knees or knees and hips averaging two and one-half years in duration were submitted to manipulation after conservative measures had failed to correct the deformities. Fourteen of these patients are now walking with straight legs.

Medicine and Machinery—Today we are witnessing the apotheosis of the machine in human life and it is not surprising to find that medicine, like other spheres of action is being mechanized. The public has come to believe that machinery is revolutionizing the healing art and is dispensing with the need for human judgment. It is true that the introduction of instruments of precision into medicine has been of great service but the interpretation of the results obtained by them in the individual case still demands wisdom and experience on the part of the doctor. Where the machine is greater than the man the patient perishes. A large section of the public does not understand this. It has such an incorrigible love for apparatus, and what it produces, that it hailed with acclamation a box of gadgets, constructed in defiance of all scientific principles which claimed to hand out an exact diagnosis and even the appropriate treatment, and thus make the application of so fallible a thing as the human mind unnecessary. Failing the reduction of medicine to machinery, the public seeks salvation in the specialist and the expert, and the more apparatus, and the more complicated, employed by these, the greater its confidence.—Lord Horder. *The Clinician's Function in Medicine* *New York State J. Med.* 36 843 (June 1) 1936.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS IECHE, Secretary

USE OF THE TERMS "STERILE," "STERILIZE" AND "STERILIZATION"

In an official communication from the Food and Drug Administration of the U. S. Department of Agriculture, the Council was asked to express an advisory opinion as to the use of the terms 'sterile,' 'sterilize' and 'sterilization,' especially when it appears on the labels of agents used 'for sterilization of the skin.'

The Council adopted the following statement and authorized its transmission to the Food and Drug Administration:

The Council on Pharmacy and Chemistry has formally gone on record as disapproving of the use of the terms 'sterile,' 'sterilize' and 'sterilization' in a bacteriologic sense other than in their correct scientific significance, i. e., meaning the absence or destruction of all micro-organisms. These terms are not relative and to permit their use in a relative sense not only is incorrect but opens the way to abuse and misunderstanding. It is questionable that there are any chemical agents tolerated by the skin which will produce sterility although there are some which will reduce the bacterial flora of the skin to such an extent that they may properly be described as disinfecting agents. For such agents there is no objection to the use of the terms 'disinfecting,' 'bactericidal' and 'bacteriostatic.'

Reference was also made to the decision of the Committee on Foods, which is as follows:

USE OF TERMS 'STERILE,' 'STERILIZED' AND 'STERILIZATION'

The terms *sterile*, *sterilized* and *sterilization* shall be used in food advertising in their correct scientific significance only. Foods processed to be free of pathogenic organisms or to keep sound and wholesome are not necessarily sterile, i. e., free from viable micro-organisms.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary

LARSEN'S "FRESHLIKE" STRAINED APRICOTS

Manufacturer—The Larsen Company, Green Bay, Wisconsin

Description—Canned, sieved apricots

Manufacture—Apricots heated, sieved and canned in vacuum. The cans are processed and promptly cooled.

Analysis (submitted by manufacturer) —

| | per cent |
|--|----------|
| Moisture | 87.6 |
| Total solids | 12.4 |
| Ash | 0.8 |
| Fat (ether extract) | 0.2 |
| Protein (N X 6.25) | 0.7 |
| Crude fiber | 0.6 |
| Carbohydrates other than crude fiber (by difference) | 10.1 |

Calories—0.5 per gram, 14 per ounce

Vitamins—The method of preparation, sieving and processing are considered efficient for protecting the vitamins.

Claims of Manufacturer—For all table uses of strained apricots but especially intended for infants, children and convalescents and for special 'smooth' diets. Only warming is required for serving. The natural mineral and vitamin values are retained in high degree.

KING BRAND SYRUP

Manufacturer—Mangels-Herold Company, Baltimore

Description—A table syrup, corn syrup with refiners' syrup and cane sugar

Manufacture—The ingredients are purchased from the manufacturers are mixed in formula proportions, heated from thirty to forty minutes at 77 C, strained, and filled into friction top lacquered cans

| Analysis (submitted by manufacturer) — | per cent |
|--|-------------|
| Moisture | 19.1 |
| Ash | 0.4 |
| Protein (N × 6.25) | 0.1 |
| Reducing sugars as dextrose | 36.4 |
| Sucrose | 11.7 |
| Dextrins (by difference) | 32.3 |
| Color | Natural |
| Specific gravity @ 20 C | 1.397 |
| Specific gravity @ 60 F | 41.2 Beaume |

Calories—3.2 per gram 91 per ounce

Claims of Manufacturer—A syrup for cooking baking and table use.

WHITE SWAN PINEAPPLE JUICE

Distributor—Waples Platter Company, Fort Worth Texas

Packer—Hawaiian Pineapple Company, Ltd, San Francisco

Description—Canned Hawaiian Pineapple Juice retaining in high degree the natural vitamin content the same as Dole Hawaiian Finest Quality Pineapple Juice (Unsweetened) (THE JOURNAL, June 3 1933 p 1769)

"WONDER" BRAND EVAPORATED MILK

Manufacturer—Meyenberg Milk Products Company, Salinas Calif

Description—Unsweetened sterilized evaporated milk. The same as Meyenberg All Pure Brand Evaporated Milk (THE JOURNAL, Feb 22, 1936 p 617)

ANNUAL MEETING OF THE COMMITTEE
ON FOODS

The annual meeting of the Committee on Foods was held in the Palmer House, Chicago, March 12, 1936. There were present

| | |
|----------------------|---------------------|
| Dr E M Bailey | Dr G F Powers |
| Dr F C Bing | Dr Lydia J Roberts |
| Dr Joseph Brennemann | Dr Mary Swartz Rose |
| Dr Morris Fishbein | Dr Russell M Wilder |
| Dr P C Jeans | |

Dr Fishbein was elected Chairman of the Committee and Dr Jeans Vice Chairman. Among the topics discussed during the meeting, the following may be of interest to physicians and to manufacturers

The Scope of the Committee—The Committee discussed at considerable length the question of the scope of its work, the food products to be considered and those which might well be classed as requiring no special consideration by the Committee. It was the consensus of opinion that a number of food products which now stand accepted present no special nutritional problems which necessitate their continued consideration. It was decided that the list of accepted foods be examined to determine which food products should continue to be considered as falling within the purview of the Committee. A statement of the Committee's action will be published shortly

The Committee also voted that the period of acceptance shall be limited to two years, at the end of which time products shall be considered again

Fortification of Foods Other than Fortification of Milk with Vitamin D—Fortified foods have not previously been defined by the Committee. While no definition is attempted at the present, it is understood that in general a fortified food is one in which the percentage of mineral elements or the unitage of vitamins has been made significantly beyond that of the same food as it exists in nature. This enhancement of

the vitamin (or inorganic salt) content is brought about by the addition of a concentrate or rich source of the material or the actual salts or vitamins themselves

The Committee discussed at considerable length the problems involved in the addition of vitamin preparations to foods. While the Committee has shown by its actions that it is not opposed to the addition of vitamin concentrates to foods under all circumstances, yet it desires that such fortification shall not be made unless (a) it has been demonstrated that there is a need for such fortification and (b) unless suitable experimental evidence shows that the fortified food suitably serves the purpose desired. It was voted that the policy of the Committee in general shall be as follows

'If in exceptional cases a general need for vitamin (or inorganic salt) intake above that afforded by the usual mixed diet of common foods is indicated the Committee shall require (a) acceptable and convincing evidence that there is a need for enhanced amounts of vitamins (or inorganic salts) in the general food supply, and (b) that the food vehicles proposed for the distribution of such vitamins (or inorganic salts) are suitable and appropriate'

In line with the foregoing policy it was voted that manufacturers of accepted vitamin D fortified products including breads and cereals be requested to produce evidence meeting points a and b above before a date to be specified. If satisfactory evidence is not forthcoming, the Committee will be obliged to rescind acceptance of such products

Significance of Terms Excellent, Good and Fair to Denote the Relative Value of Food as Sources of Vitamins—The Committee discussed the possibility of preparing suitable tables to give the value of foods as sources of the vitamins. The majority of tables available at the present time contain the well known plus and minus marks, which are hardly suitable for refined dietary calculations

Vitamin E—The Committee again considered the claims for vitamin E and concluded that no adequate scientific data are available which establish the role of vitamin E in human dietetics. It is a ruling of the Committee that neither claims for vitamin E nor mention of the vitamin shall appear on food labels or in advertising for accepted foods addressed to the public. It was the consensus of opinion of the Committee that mention of vitamin E in advertising addressed to the profession of accepted food products shall not be permitted if inferentially such advertising recommends the use of the preparation because of its vitamin E content

Special Purpose Foods—The class of foods called "Special Purpose Foods" was defined by the Committee three years ago. In this group are included a number of products specially intended for carbohydrate restricted diets. The referee reported on the question of the labeling of such products. At the present time the importance of carbohydrate restricted diets for diabetic patients is probably secondary to the usefulness of ketogenic diets in the treatment of pyelitis and cystitis and other infections of the urinary tract. The value of water packed foods is limited to a large extent to people who need to know the amount or composition of what they eat more accurately than most people. It is therefore important that the composition shall be stated on the label and expressed in percentages. The referee suggested that the language of the ruling be changed to have the mineral content and also the vitamin unitage recorded in units per hundred grams. It was pointed out that carbohydrate should preferably be expressed in terms of available carbohydrate, although the difficulties of chemically defining available carbohydrate are realized.

The following addendum to the decision of the Committee regarding the labeling of special purpose foods was presented by the referee and adopted by the Committee

"In the case of water packed fruits and vegetables the designation 'Special Purpose Food' will not be required provided it is replaced by a statement to the effect that this food or these foods are prepared with special reference to the needs of invalids and have no added salt or sugar. The vitamin and mineral content should be stated on the label as well as the calories per gram or ounce and the grams each of total carbohydrate, protein, and fat per hundred gram weight of fruit or vegetable and liquid'

HORNER'S SYNDROME

A distinguished Swiss ophthalmologist, Johann Friedrich Horner, described in 1869 a symptom complex generally known by his name. The syndrome is characterized by sinking in of the eyeball, drooping of the upper lid, slight elevation of the lower lid, constriction of the pupil, narrowing of the palpebral fissure, and certain changes in the vasomotor and sudorific activity of the skin of the face. With the developments in neurosurgery and the ever increasing number of industrial and motor accidents this syndrome is now more frequently observed than formerly. Previous to Horner's clinical observations, experimental work on laboratory animals that would in part explain the syndrome had been accomplished by several workers. Claude Bernard, who in 1852 sectioned the cervical portion of the sympathetic trunk, had observed retraction of the eyeball and narrowing of the palpebral fissure. Budge had found that the sympathetic nerves to the head arise in the first and second dorsal segments of the spinal cord. Langley had identified the levels in the cord at which the various types of sympathetic fibers arise. He had found that vasomotor control to the conjunctiva and to the external ear comes from the third and fourth dorsal segments, and the pilomotor fibers to the face from the fifth and sixth dorsal segments. Langley also discovered that the preganglionic fibers to the dilator pupillae muscle end in the superior cervical ganglion and establish synaptic relations there with the postganglion fibers that go direct to the pupillary muscles. Although Horner in his original paper, as translated by Fulton,¹ did not refer to this experimental work, his clinical observations were in correlation with the physiologic data. Horner's priority to the discovery seems unquestioned today, in 1838, however, Hare, a house surgeon at the Stafford County General Infirmary, had described the clinical syndrome and the pathologic changes found post mortem in a case of carcinoma that involved the nerves and blood

vessels on the left side of the neck and the phrenic and lower cervical ganglions of the sympathetic. Hare understood the connection of the tumor with the paralysis of the arm in his case but apparently did not understand the relation of the drooping eyelid to the sympathetic nervous system. Had Hare been familiar with the experimental work of Claude Bernard, Crunkshank, Petit and others, he might have made the discovery which later was made by Horner.

Horner's syndrome may follow disease or injury to the brain stem, to the lower part of the cervical portion of the spinal cord or the upper part of the dorsal portion or to the superior cervical sympathetic ganglion or the postganglionic nerves, as well as to some of the nerve roots. There is some difference of opinion about the exact etiology of each of the elements of the symptom complex. Certain constituents of the typical syndrome are not present in all cases. This may be due to the destruction of certain nerve fibers in some cases while in other cases these fibers escape. Cobb and Scarlett² have found that the most severe oculopupillary syndromes are those due to injuries of the seventh and eighth cervical and first dorsal nerve roots, less severe symptoms are produced by injuries to the cervical portion of the sympathetic trunk, and the least pronounced symptoms follow definite injuries to the spinal cord.

According to DeJong³ the most frequently mentioned causes of Horner's syndrome are tumor of the spinal cord, or syringomyelia at the level of the seventh or eighth cervical or first thoracic segment of the spinal cord. Other causes may be cervical tumor or enlarged lymph nodes, cervical rib, cervical pachymeningitis, aortic aneurysm, mediastinal tumor, disease of the pulmonary apices, radiculitis, disease of the esophagus and adenoma of the thyroid gland. The symptom complex may follow trauma, especially bullet or stab wounds or surgical operations on the cervical portion of the sympathetic chain and occasionally on the thyroid or the phrenic nerve. Horner's syndrome may develop in conjunction with lesions in the brain stem or in the midbrain or cortex, it has been reported as occurring in epidemic meningitis, epidemic encephalitis, anterior polyneuritis and mitral stenosis. Jacob⁴ reported that cases of tumor of the upper portion of the pulmonary sulcus are characterized by Horner's syndrome. In his recent paper, De Jong reports ten cases illustrating different causative factors of the syndrome observed in one year at the University Hospital in Ann Arbor. Paralysis of the cervical portion of the sympathetic nervous system is probably more frequent than reports in medical literature indicate.

MESENTERIC LYMPHADENITIS

Acute mesenteric nontuberculous lymphadenitis is a clinical entity is a comparatively recent concept. The lymph nodes of the mesentery received but scant attention from the surgeon, probably because they are neither palpable nor visible except in the presence of lymphangitis or regional involvement secondary to inflammation, malignant tumor or tuberculosis of the bowel. The mesenteric lymph nodes may show but little enlargement with severe inflammation of the appendix or the gallbladder. Enlarged mesenteric lymph nodes in the young were formerly considered invariably tuberculous. Wilensky¹ in 1920 and Heusser² in 1923 described cases in which the enlarged lymph nodes were definitely involved by simple nontuberculous inflammation. The later reports of Wilensky and Hahn³ in this country and of Pribram⁴ in Germany established the existence of acute mesenteric lymphadenitis as an independent clinical entity. The condition is seen preponderantly in children but also in young adults. Following an acute infection, most frequently tonsillitis, a lymphangitis develops within the peritoneal cavity which leads to enlargement of the mesenteric lymph nodes, injection of the leaves of the mesentery, and a hyperemia of the intestinal serosa. The ileocecal segment appears to be the seat of predilection. The clinical symptoms resemble closely those of acute appendicitis. At operation a small amount of serous or turbid fluid, a normal appendix and swollen lymph nodes running up to the root of the mesentery are found. The nodes vary in size and may attain that of a bean. Following the appendectomy, the clinical signs subside in the course of a few days.

In a recent analysis of cases observed in Pribram's clinic during the last ten years, Kleiber⁵ points out that after an appendectomy cases of mesenteric lymphadenitis, unlike those of acute appendicitis, show a tendency to recurrence of attacks of abdominal pain. Particularly characteristic is the coincidence of these attacks with repeated attacks of sore throat. The inflammation subsides in the course of a few days. Occasionally there remains a tenderness in the ileocecal region leading to an erroneous diagnosis of postoperative adhesions. The course of the disease is mild. A few cases have been observed, however, with a stormy onset and symptoms of acute peritonitis, such as high fever, prostration, abdominal distention, vomiting, constipation and a pronounced leukocytosis. At operation, diffuse redness of the distended intestinal

loops, a turbid exudate, fibrinous deposits and gluing together of the intestinal loops were found. The appendix was unaltered or only slightly involved. The lymph nodes were swollen and the leaves of the mesentery hyperemic. The prognosis in these cases is grave, the patient dying of peritonitis in the course of a few days regardless of whether or not an operation is performed. In a few of the cases streptococci were isolated from the lymph nodes. Kleiber stresses that a careful history almost never fails to bring out the existence of pathologic tonsils. The tonsillar infection is considered the primary focus from which streptococci reach the mesenteric lymph nodes by either the hematogenous or the enteric route (organisms swallowed with saliva). In his report on eighty-six cases of mesenteric lymphadenitis personally observed, in seventy-eight of which operation was performed, Coleman⁶ stresses the association of this condition with acute respiratory infections in the winter months and with intestinal infection in the summer. He likewise found the tonsils "usually infected and enlarged." Goldberg and Nathanson⁷ isolated hemolytic streptococci from every one of the throats of patients when cultures were made. They have isolated the same organism from a small percentage of nodes removed.

The treatment of the condition is surgical intervention. Accurate preoperative differentiation of mesenteric lymphadenitis and acute appendicitis is not possible. Tonsillectomy is definitely indicated in cases in which postoperative attacks of abdominal pain recur.

RECOGNITION OF CONGENITAL HEART DISEASE

Recently McGinn and White¹ have reviewed the records of 7,500 necropsies at the Massachusetts General Hospital to determine the frequency with which congenital heart disease has been seen there since 1895. Congenital heart disease was found sixty-seven times, representing an incidence of 0.9 per cent. About one third of the patients, or twenty-one, were infants under 1 year of age, 3,400 of the necropsies were performed in the last fifteen years. The clinical records of the forty-one cases in which there were congenital lesions were studied in detail. The incidence of congenital heart disease in this group was 1.2 per cent. It is therefore suggested that more congenital defects are recognized when the hearts are examined with such lesions especially in mind. The clinical records showed that a correct diagnosis of this lesion had been made seven times, four in adults and three in infants under 1 year of age. The cases consisted of three with

idiopathic congenital hypertrophy, two with interventricular septal defect, one with the tetralogy of Fallot, and one with pulmonary stenosis. In five other patients, including one infant, the correct diagnosis had been suspected during life. These twelve cases therefore represent the correct or suspected diagnosis in 29 per cent of the congenital lesions coming to necropsy in the last fifteen years.

In reviewing these cases with the aim of improving the percentage of correct diagnoses, a large group of lesions were encountered, namely, those of defective valve structure and abnormal coronary vessels, which at the present time provide no adequate evidence to suggest their presence. Certain clinical clues, however, can be recognized, according to the authors, as affording suggestive evidence for the recognition of some of the congenital lesions. The most characteristic clinical sign of patent ductus arteriosus is a typical murmur. It is generally heard best in the second left interspace and is a harsh, humming murmur with a sound similar to a mill wheel or the machine-like purr of a large motor. It is continuous with accentuation during systole and may be accompanied by a thrill. X-ray examination is generally characteristic. The most important evidence of interventricular septal defects is the presence of a harsh systolic murmur heard best at the third interspace and more or less confined to that immediate area but frequently heard in the back between the scapulae. There is usually a thrill accompanying the murmur. X-ray examination fails to show gross enlargement in spite of the loud murmur. Blunting of the apex is sometimes present. Idiopathic congenital hypertrophy of the heart refers to enlarged and dilated hearts observed at birth or early infancy and for which no cause can be discovered. There are five signs which when they occur in association, permit the diagnosis of the tetralogy of Fallot with a high degree of certainty: cyanosis of the lips, cheeks, ears, fingers and toes, clubbing of the fingers and toes, a loud systolic murmur heard best in the pulmonary valve area and in the third left interspace, extreme right axis deviation seen in the electrocardiogram, and, finally, disclosure on x-ray examination that the heart is boot shaped, owing to enlargement of the right ventricle without enlargement of the pulmonary artery. Coarctation of the aorta can often be recognized by five diagnostic criteria. These are hypertension occurring in children and young adults, a blood pressure higher in the arms than in the lower extremities, conspicuous blood vessels of the trunk, especially of the intercostal and mammary arteries, a harsh systolic murmur at the base of the heart and in the back, and evidence of left ventricular hypertrophy on x-ray examination. The presence of symptoms of persistence of a right aortic arch is dependent on the degree of constriction that might be caused. A heart with a "water bottle" shape should be sufficient to suggest a *cor biatricum trilobulare*. Interauricular

septal defects are common at necropsy. Four observations suggest this anomaly: late cyanosis, a large pulmonary artery, enlarged lung hilus shadows and an enlarged right ventricle seen radiographically, right axis deviation in the electrocardiogram, and paradoxical embolism.

While admittedly the correct clinical diagnosis of congenital anomalies of the heart is difficult, an awareness of their possibility and the knowledge leading to a correct diagnosis should increase the frequency of diagnosis previous to necropsy.

Current Comment

DOCTORS AND DIAPLEX

In a recent trial the federal government was defeated in its attempt to prove one Horace Wayne Pierce, manufacturer and shipper of a herb tea called "Diaplex," guilty of fraud under the criminal clause of the Food and Drugs Act. Diaplex, the dried leaves and stems of *Atriplex canescens* (salt bush), is offered as a specific for diabetes. The advertising exaggerates the dangers of insulin and dwells on the simplicity of taking Diaplex. The government lost its case principally because of the premature enthusiasm of a physician for the nostrum. As told in a brief summary of the case issued by the United States Department of Agriculture, the government contended that the falsity of the claims made for Diaplex as a remedy for treating diabetes was fully proved. The breakdown in the government testimony came when two witnesses—one a doctor and the other a layman—admitted the writing of complimentary and optimistic letters to the manufacturer. Both these witnesses testified nevertheless that they had been misled, as the herb tea turned out to be worthless in their later experience. At the trial Pierce claimed that he depended on these letters as expressions of opinion from persons competent to judge the effects of his treatment. In the face of this testimony, the jury was not convinced of the fraudulent intent, which, under the law, must be shown in all criminal cases involving curative claims for medicines. The testimony of physicians called by the government that Diaplex could not affect the course of diabetes was entirely nullified by the careless endorsement of one physician. Endorsements given by physicians to "patent medicine" vendors, either carelessly or wilfully, are invariably distorted into bait for the uncritical patient as a means of luring him away from proved methods of treatment. The case of Diaplex should serve as a warning to the physician against haste in judgment of therapeutic results. The difficulty of evaluating remedies for arthritis, diabetes, nephritis, hypertension and similar chronic conditions should be realized. The lack of suitable controls is apparent in all these hasty enthusiasms which lead doctors into writing or voicing commendation before time has truly tested the results. Then, like the ghost in Hamlet, their testimonials come back in after years to haunt them.

Association News

THE ATLANTIC CITY SESSION

Eighty-Eighth Annual Session to Be Held in June

The American Medical Association will hold its Eighty-Eighth Annual Session in Atlantic City, N. J., June 7 to 11, 1937.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ARKANSAS

District Meetings—The Ninth Councilor District Medical Society was addressed in Eureka Springs, June 2, by Drs. Charles T. Chamberlain, Fort Smith, on "Mechanism of Heart Beat and Electrocardiography", Francis T. H. Doubler, Springfield, Mo., "Minutiae of Thyroid Signs and Symptoms", George B. Fletcher, Hot Springs, "Medicine Forty Years Ago and Now", Guy D. Callaway, Springfield, "Cardiac and Renal Complications of Pregnancy", Fred R. Brooksher, Fort Smith, "The Treatment of Certain Complications of". Dr. Brooksher also addressed the Eighth Councilor District Medical Society, May 28. Other speakers were Drs. Robert Caldwell, "Sinusitis in Children", Allie C. Kolb, "Problem of Caring for the Mentally Abnormal", and Augustus C. Shupp, "Surgical Treatment of Tuberculosis". All are of Little Rock.

CALIFORNIA

Hospital News—A symposium on the use of analgesics, hypnotics and sedatives was presented at the meeting of the staff of the Peralta Hospital, Oakland, June 25. Speakers included Drs. Olin H. Garrison, Frank H. Bowles, Charles C. Hall, Leonard B. Barnard, Thomas I. Buckley, Lester B. Lawrence and Burton W. Adams. The staff of Mary's Help Hospital, San Francisco, gave a banquet, June 27, in honor of five members of the house staff who are leaving. The guests of honor were Drs. Charles A. Rethers, Dwight A. Mater, John J. McDevitt, Alexander Rogozen and John B. Thielen.

COLORADO

Society News—Dr. Harold L. Hickey was chosen president of the Colorado Otolaryngological Society at its annual meeting in Denver, May 2. Dr. Herman I. Laff, secretary, and Dr. Harry L. Whitaker, treasurer, all of Denver. At a meeting of the Medical Society of the City and County of Denver, May 16, Dr. William J. Kerr, San Francisco, discussed "The Anxiety State in Practice," and Dr. William F. Rienhoff Jr., Baltimore, "Diagnosis and Treatment of Carcinoma of the Lung."

Fellowships in Psychiatry—The Commonwealth Fund has renewed its appropriation to provide fellowships for graduate training in psychiatry at the University of Colorado Psychopathic Hospital, Denver. Four fellowships of three years' duration have been made available, two beginning in the fall of 1936 and two in 1937. Dr. Marion B. Durfee, who graduated from the University of Colorado School of Medicine, Denver, in 1934 and completed an internship at Ancker Hospital, St. Paul, and Dr. Julius M. Wallner, who graduated from the University of Pennsylvania in 1935 and who has completed an internship at the Colorado General Hospital, Denver, have been appointed to begin their fellowships in September.

CONNECTICUT

Cancer Survey Under Way—To assist in a state survey of cancer prevention, Dr. Matthew H. Griswold, Kensington, health officer of the town of Berlin, has been appointed public health physician in the state department of health to specialize in cancer work, a newly created position. The state survey was made possible with funds granted to the state health department by the 1935 legislature under a bill sponsored by the Connecticut State Medical Society. A statistical study of cancer cases now under way by Mr. Herbert F. Hirsche was the

first step in the survey. Dr. Griswold, who is resigning as health officer and relinquishing his private practice, will cooperate with the tumor committee of the state medical society in its cancer program. About sixteen clinics are now operating in general hospitals in the state as a result of the society's program, and others are planned.

GEORGIA

Society News—Dr. Gerry R. Holden, Jacksonville, Fla., discussed "Treatment of Uterine Hemorrhage" before the Fulton County Medical Society in Atlanta, June 18. At a meeting of the Atlanta Clinical Society, May 27, Drs. James N. Brawner Jr. read a paper on "Clinical Aspects of Certain Ovarian Tumors", James Mason Baird, "Ophthalmologic Findings in Common Medical Conditions," and John D. Martin Jr. presented a case report on "Congenital Absence of Dorsal Fixation of the Mesentery of the Small Intestine."

ILLINOIS

Two Cases of Rocky Mountain Spotted Fever—The state health department reported that two cases of Rocky Mountain spotted fever had recently been recognized in Illinois. One of the patients, a cattle raiser's wife, living on a farm near Canton, told of finding a tick on her head nine days prior to the onset of her illness. Shortly before she had been working with sick steers recently purchased through the Peoria stockyards, where they had been shipped from the West. Apparently the tick had transmitted the disease to this patient, it was said. The other patient, a filling station attendant at Clinton, had no recollection of a tick or other insect bite, presumably an infected insect had been brought along by an automobile party, the department reported.

Chicago

Society News—Dr. Richard M. Davison was chosen president of the Chicago Tuberculosis Society at its annual meeting recently. Dr. George de Tarnowsky was chosen president-elect of the Chicago Gynecological Society at its annual meeting, June 12, and Dr. Harold O. Jones was installed as president.

University News—The cornerstone of a new medical and dental laboratory building of the University of Illinois College of Medicine was laid June 4. Wilbur R. Tweedy, Ph.D., has been appointed professor and head of the department of physiologic chemistry at Loyola University School of Medicine, succeeding the late William C. Austin, Ph.D. He has been associated with the medical school since 1925.

Five "Voice of Safety" Cars—The police bureau of accident prevention has equipped five automobiles with loud speakers to spread a message of traffic safety, according to the *Chicago Tribune*. Each car, manned by two specially trained policemen, will tour the city, particularly in the vicinity of schools, announcing the "do's" and "don'ts" of safe driving and safe walking. Motorists and pedestrians committing minor infractions will be warned politely through the loud speakers.

INDIANA

Personal—Dr. Argal E. Hubbard, formerly superintendent of the Peoria Municipal Tuberculosis Sanitarium, Peoria, Ill., has been named to a similar position at the Marion County Tuberculosis Hospital, Indianapolis, to succeed Dr. William McQueen, who resigned June 1 on account of ill health. Dr. Orlando W. Brownback, Pendleton, recently observed his ninetieth birthday.

Society News—Dr. Paul D. Crimm, Evansville, addressed the Gibson County Medical Society at Princeton, June 8, on "Surgical Treatment of Pulmonary Tuberculosis." At a meeting of the Dearborn-Ohio County Medical Society in Lawrenceburg, May 28, Dr. William M. Doughty, Cincinnati, discussed "X-Rays and the General Practitioner." The Marshall County Medical Society was addressed in Plymouth, June 10, by Dr. George S. Bond on "Heart Sounds with Their Interpretation." At a meeting of the Indiana State Pediatric Society, June 8, Dr. Philip C. Jeans, Iowa City, discussed nutrition, and Dr. Irvine McQuarrie, Minneapolis, edema.

IOWA

Personal—Dr. James F. Edwards has retired as head of student health service and the department of hygiene, Iowa State College, Ames, on account of age, and has been succeeded by Dr. John G. Grant, his assistant for several years. Dr. John M. Hayek, Cedar Rapids, has been named pediatrician for the division of child health and health education for the state department of health, this is a newly created position.

financed with funds appropriated under the Social Security Act — Dr Louis J. Leech, West Branch, has been made an honorary life member of the Iowa State Medical Society.

County Society Exhibit at Centennial—A medical and historical exhibit was opened to the public, June 26 by the Scott County Medical Society as a part of the centennial of the incorporation of Davenport as a town. The exhibit, which takes up the lobby and mezzanine floors of the Union Bank Building, will run three weeks, although the centennial celebration of the community is expected to continue into January, it is reported. At the opening, Dr William W. Bruer, director, Bureau of Health and Public Instruction, American Medical Association, Chicago, gave an address entitled "Popular Beliefs That Are Not So," and a sound motion picture, showing animal experimentation in the conquest of disease was displayed. During the run of the exhibit a member of the Scott County Medical Society is to give a public address each evening. The display depicts the growth of the county medical society since its founding in 1856 and shows contrasting photographs of the hospitals of Davenport when they were first established and as they are today, including all historical data on their growth. Famous figures of medical history such as Pasteur, Ehrlich and Lister are represented in historical material and photographs. Another interesting feature is a reproduction of the operating room of a modern hospital with life-sized artificial models performing the duties of hospital personnel.

LOUISIANA

Society News—The Ouachita Parish Medical Society was host to the Rapides Parish Medical Society at a banquet May 7. Speakers were Drs Albert L. Culpepper on "Treatment of Acute Empyema", Ford A. Thomas "Treatment of Lobar Pneumonia with Specific Serum," and Ralph Lambert "all from Alexandria, Treatment of Varicose Veins."—The Orleans Parish Medical Society held a meeting at the U. S. Marine Hospital, June 22, speakers were Drs William L. Smith on "Helium and Oxygen Therapy," Richey L. Wraugh, "Fractures of Long Bones and Methods of Treatment," Automo Mayoral "The Shrunken Lung," John A. Trautman, "Wilms Tumor with Report of Two Cases," and Waldemar R. Metz "Plephthiasis of Scrotum Following Bilateral Inguinal Glandular Tuberculosis." Dr Edward H. Rynearson Rochester Minn. addressed the society, June 8, on "Clinical Syndromes Resulting from Dysfunction of the Endocrine Glands."—Dr Philip J. Carter was elected president of the New Orleans Gynecological and Obstetrical Society, May 21.

MAINE

Society News—At a meeting of the Kennebec County Medical Association in Gardiner, May 22, speakers included Elmer W. Campbell, Augusta, who discussed "The New Cosmetic Law", Dr Herbert R. Kobes, Augusta "Social Security Act," and Dr Shields Warren, Boston, "The Pathology of Malignant Disease with Relation to Treatment."—Dr Stanwood E. Fisher addressed the Portland Medical Club recently on "Inflammation of the Nasal Sinuses." Dr DeForest Weeks also addressed a recent meeting of the club on chronic arthritis and sciatica.—The York County Medical Society was recently addressed in York by Dr Allan L. Davis, Boston, among others, on fractures.

MARYLAND

Dr Uhlenhuth Awarded Van Meter Prize—Eduard Uhlenhuth, Ph.D., professor of anatomy, University of Maryland School of Medicine, Baltimore, was awarded the Van Meter Prize of the American Association for the Study of Goiter at its annual session, June 9, for his thesis on "Isolation of the Thyreo-Activator Hormone from the Anterior Lobe of the Bovine Pituitary Gland." Dr Uhlenhuth received his degree of doctor of philosophy at the University of Vienna in 1909. He became associated with the University of Maryland in 1925.

MASSACHUSETTS

Portrait of Dr Leary—The class of 1906 at Tufts College Medical School recently presented to the school a portrait of Dr Timothy Leary, medical examiner for the southern district of Boston. Dr George S. Foster, Manchester, N. H., president of the class, made the presentation. John A. Cousens, LL.D., president accepted it on behalf of the college and turned it over to Dr Albert Warren Stearns, dean of the medical school. Speakers included Drs Louis E. Phaneuf, Frank H. Dunbar and

Francis P. McCarthy, all of Boston. Dr Leary was assistant professor of pathology and bacteriology at Tufts from 1897 to 1900 and professor from 1900 to 1929, when he became emeritus professor.

Personal—Dr Benjamin Sachs, assistant professor of ophthalmology, has been appointed professor of ophthalmology at Tufts College Medical School, Boston.—Dr William O. Faxon, Stoughton, was guest of honor at a dinner, May 1, in celebration of his completion of sixty years in the practice of medicine, he has been medical examiner of Norfolk County for forty-two years. A silver platter, bearing the engraved names of those who participated in the celebration, was presented to Dr Faxon.—Philip Drinker, Ch. E., has been promoted from associate professor to professor of industrial hygiene at Harvard University School of Public Health, Boston.—Dr John H. White, clinical professor of ophthalmology, Harvard University Medical School, Boston, was awarded the honorary degree of doctor of science by Bucknell College at its eighty-sixth commencement at Lewisburg, Pa., recently.

MICHIGAN

Rabies—The Detroit Department of Health has requested the police to enforce the ordinance requiring that all dogs be kept on a suitable leash in an effort to prevent the spread of rabies in the city. The department urges the vaccination of all dogs in the area bounded on the north by Eight Mile Road, on the east by Dexter Boulevard, on the south by Fenkell Avenue and on the west by Wyoming Avenue. Two rabid dogs were reported during April six during May and three up to June 13.

Portrait of Dr LeFevre—A life-sized oil portrait of Dr George I. LeFevre was one of three unveiled at a ceremony in Mercy Hospital, Muskegon, June 1, in appreciation of his many years interest in the development of the institution. Dr LeFevre has been identified with Mercy Hospital since its founding in 1903, serving as its president, chief of staff and chairman of the advisory committee. He has been president of the Muskegon County Medical Society and for several years was counselor of the eleventh district. For many years a member of the Michigan State Board of Registration in Medicine he served as chairman for sixteen consecutive years. He was president of the Michigan State Medical Society in 1933.

MINNESOTA

State Medical Election—Dr Alfred W. Adson, Rochester, was elected president of the Minnesota State Medical Association at its annual meeting in May. Other officers include Drs Henry W. Goehrs, St. Cloud, and Douglas P. Head, Minneapolis, vice presidents, Edward A. Meyerding, St. Paul, secretary, and William H. Condit, Minneapolis, treasurer. The next annual session will be held in St. Paul. A revised constitution was provisionally adopted. One of the major changes proposed in the new constitution is the election of a speaker for the house of delegates. In anticipation of the permanent establishment of this office, Dr Oscar E. Locken Crookston, was elected temporary speaker. Dr Robert G. Green, professor of bacteriology and immunology, University of Minnesota School of Medicine, Minneapolis, received the medal presented annually by the Southern Minnesota Medical Association for the best scientific exhibit. His subject was tularemia and certain filtrable viruses. Sir Henry Wellcome, who founded the Wellcome Research Institution, London, was present at the meeting.

Retiring Faculty Members Honored—A testimonial dinner was held, June 10, in honor of the following members of the faculty of the University of Minnesota School of Medicine, who are retiring on account of age:

Dr James T. Christison, associate professor of pediatrics
Dr Charles H. Mayo, professor of surgery
Dr Charles A. Erdmann, associate professor of anatomy
Dr James S. Giffillan, associate professor of medicine
Dr Thomas B. Hartzell, lecturer in medicine
Dr John T. Rogers, associate professor of surgery
Dr John L. Rothrock, professor of obstetrics and gynecology
Dr Franklin R. Wright, associate professor of urology

The retirement of Dr Elias P. Lyon as dean of the medical school was announced some time ago. At the dinner, a portrait of Dr Lyon, the gift of heads of the department and divisions of the medical school, was presented to the medical school by Dr Harold S. Diehl, his successor as dean. Dr William J. Mayo accepted it on behalf of the board of regents. The establishment of the Elias Potter Lyon Lectureship was announced on this occasion, Dr Adam M. Smith making the announcement for the Medical Alumni Association. President Lotus D. Coffman presided and Dr Jennings C. Litzberg was toastmaster.

MISSOURI

Dr Marriott to Be Dean at California—Dr Williams McKim Marriott, since 1923 dean of Washington University School of Medicine, St. Louis, has resigned to become dean and professor of research medicine at the University of California Medical School San Francisco. Until a new dean has been appointed at Washington, the affairs of the medical school will be administered by a committee of three faculty members. Dr David P. Barr, head of the department of internal medicine, Philip A. Shaffer, Ph.D., head of the department of biologic chemistry and Dr Curtis A. Graham, head of the department of surgery. Dr Marriott will be succeeded as professor of pediatrics and physician in chief of the St. Louis Children's Hospital by Dr Alexis F. Hartmann, associate professor of pediatrics at Washington. Dr Marriott, who is 51 years of age, graduated from Cornell University Medical School in 1910. He began his teaching career as assistant in chemistry at the University of North Carolina. Subsequently, until he became professor of pediatrics at Washington University School of Medicine he taught at Cornell, Washington University and Johns Hopkins. He served on the Council on Pharmacy and Chemistry of the American Medical Association from 1926 to 1930. He is the author of "Recent Advances in Chemistry in Relation to Medical Practice" and "Infant Nutrition." Dr Langley Porter, who has been dean of the University of California Medical School since 1927, reached the retirement age in 1935, but the board of regents extended his term for one year.

NEW JERSEY

Society News—Drs Milton Helpert and Chas Ray Murray, New York, addressed the Bergen County Medical Society, Hackensack, June 9, on "Sudden Death" and "Low Back Pains" respectively.—The newly organized New Jersey chapter of the Association of Military Surgeons of the United States held its first formal meeting at Atlantic City, June 2, during the meeting of the Medical Society of New Jersey. Speakers included Gen Harry L. Gilchrist, who discussed medical problems of gas warfare, Dr William Seaman Bainbridge, New York, progress in military medicine and surgery, and Col Jay W. Grissinger, U. S. Army, war-time medical experiences and improvements evolved from them.—A symposium on ophthalmologic subjects was presented at a meeting of the Passaic County Medical Society, Paterson, May 14, by Drs Earle C. Reynolds and Thomas M. Glasgow, Passaic, and Thomas A. Sanfacion and Manasseh Benjamin Park, Paterson.

NEW MEXICO

State Medical Election—Dr George W. Jones Clovis, was chosen president-elect of the New Mexico Medical Society at the annual session, May 7, in Carlsbad. Dr Mallory B. Culpepper, Carlsbad, was installed as president and Dr Leo B. Cohenour, Albuquerque, reelected secretary. The 1937 meeting will be in Clovis.

NEW YORK

State Society Prize Awards—At the annual session of the Medical Society of the State of New York in New York in April, Dr Karl Fischel, Saranac Lake, received the Merritt H. Cash Prize awarded by the society for an essay on "The Problem of Tuberculosis." Dr Arthur J. Bedell, Albany, received the Lucien Howe Prize for an essay on "Choroideremia."

Society News—The Dutchess County Medical Society held its May meeting at the Veterans' Administration Facility Castle Point, with the following speakers: Drs Joseph F. Wallace, on "Hospitalization in Veterans' Administration Facilities," Hubert Ivey, "Collapse Therapy in Pulmonary Tuberculosis," Guy P. Asper, "Treatment of Complications in Tuberculosis," and Samuel A. Beddall, "Pneumoconiosis from an X-Ray Standpoint."—Dr Philip L. Forster, Albany, addressed the Medical Society of the County of Albany, June 24, on "The General Practitioner and His Orthopedic Problems."

Instruction in Care of Crippled Children—The New York State Department of Health is cooperating with New York University in offering two courses to prepare persons for work with the physically handicapped. The courses are intended for public health nurses and others selected by state authorities to carry out the program of the Social Security Act as it relates to crippled children. They are to be given at the New York State Reconstruction Home at West Haverstraw, the first session from July 6 to August 14, the second

from August 17 to October 17. Information concerning appointments may be obtained from the agency in charge of administration of the Social Security Act in each state, information about the courses from Dr George G. Deaver, New York University, Washington Square New York, N. Y.

New York City

Personal—Dr Simon Flexner, member emeritus of the Rockefeller Institute for Medical Research, was elected an honorary fellow of the Royal Society of Medicine in London, May 19.—Dr John N. Evans has succeeded Dr Henry Mitchell Smith as head of the department of ophthalmology at Long Island College of Medicine. Dr Smith is professor emeritus.

Three New Health Centers—Cornerstones have been laid recently for three new health center buildings as part of a program that will eventually include thirty district centers. WPA grants and loans amounting to \$1,900,963 have made possible the construction of eight buildings immediately. Those for which cornerstones have been placed recently are in East Harlem, Chelsea Park and the Williamsburgh-Greenpoint district of Brooklyn. Construction has been begun on others in Central Harlem and the Red Hook-Gowanus section of Brooklyn, it is reported.

Eight Hour Day for City Hospital Employees—The board of aldermen voted June 17 to grant the eight hour day to employees in city hospitals. The change will add about \$1,000,000 annually to the budget of the department, it was said, but in the opinion of those supporting the bill the expense is justified because of better service to patients and reduced turnover in the hospitals. The bill's provisions may be suspended in times of emergency, it is provided. It does not affect administrative officials, medical and lay superintendents, physicians, interns, pathologists, roentgenologists, superintendents of nurses and ambulance drivers. Alderman James A. Burke, who sponsored the city law, introduced into the legislature last year a similar law affecting state hospitals, which went into effect July 1.

Dr Ewing Awarded Medal—The Philadelphia Board of City Trusts recently bestowed the John Scott Award on Dr James Ewing, professor of oncology, Cornell University Medical School, for his research in classifying tumors. The Scott award, consisting of a bronze medal and \$1,000, was given to the city of Philadelphia under the will of John Scott, a Scottish chemist who died in 1916, to reward those whose work "adds to the comfort, welfare and happiness of mankind." The original bequest was only \$4,000 and the award \$20, but by 1919 the trust had increased to more than \$100,000 and courts granted the increase in the award. Winners of the award in recent years are Philip Drinker, Ch. E. and Louis Agassiz Shaw, A. B., Boston, inventors of the artificial respirator, and Dr George R. Minot, Boston, for his introduction of the liver treatment for pernicious anemia.

NORTH CAROLINA

Personal—Dr John S. Anderson, New Bern has been appointed health officer of Craven County.—Dr William Blair Hunter, Gastonia, has been appointed health officer of Harnett County.—Dr Harold D. Brewster, clinical director of the Veterans' Administration Facility at Oteen for nine years has been transferred to the facility at Legion, Texas, and will be succeeded by Dr Carroll L. Moore, clinical director at the Legion facility.

Public Health Meeting—Dr Roderick M. Buie, Greensboro, was elected president of the North Carolina Public Health Association at the annual meeting in Asheville May 4. Among speakers were Drs James A. Hayne, Columbia, state health officer of South Carolina, on "Maternal and Child Health," Mark V. Ziegler of the U. S. Public Health Service, "Determining Community Health Needs," and Alexander C. Bulla, Raleigh, "Polymyositis and the Public."

Society News—A symposium on renal calculi was presented before the Mecklenburg County Medical Society, Charlotte, June 2, by Drs Claude B. Squires and Robert W. McKay, Charlotte, and William M. Coppridge, Durham.—Dr Staige D. Blackford, Charlottesville, Va., addressed the Guilford County Medical Society, Greensboro, June 4, on "Chronic Duodenal Ileus."—Dr Le Grand Guerry, Columbia, S. C., addressed the Buncombe County Medical Society, Asheville, May 18, on "Management of Late Cases of Suppurative Appendicitis."

OHIO

Society News—Dr Henry Wagener, Rochester, Minn., addressed the Columbus Academy of Medicine May 4, on "Vascular Lesions of the Retina," at a joint meeting with the Columbus Ophthalmological and Otolaryngological Society—Dr Oscar V. Batson, Philadelphia, addressed the Summit County Medical Society, Akron, May 5, on "Veins of the Head and Neck as Related to the Problems of Otolaryngology"—The Akron Academy of Ophthalmology and Otolaryngology was formed in April with Drs Louis E. Brown as president, Elmer L. Mather, vice president, and Chas. R. Andersen, secretary—Drs Bruce H. Douglas and David S. Braehman, Detroit, addressed the Toledo Academy of Medicine, June 5, on "Childhood Tuberculosis" and "Tuberculosis in the High Schools of Detroit" respectively—Dr Elias Potter Lyon of the University of Minnesota Medical School Minneapolis, gave the annual Alpha Omega Alpha address of the Academy of Medicine of Cincinnati, May 19—Dr Theodore T. Zuck, Cleveland, addressed the Tuscarawas County Medical Society Uhrichsville, May 14, on "Clinical Application of Recent Endocrine Studies of Human Development"—Dr Charles R. Hoskins, Athens, presented a paper on "Recent Advances in the Surgical Treatment of Facial Paralysis" at a meeting of the Athens County Medical Society, Nelsonville May 4

PENNSYLVANIA

County Society Clinic—The Westmoreland County Medical Society held its annual clinic at the Latrobe Hospital Latrobe June 3. At the morning session guest speakers were Drs John I. Wiseman, Torrance on "Symptoms of Incipient Dementia Praecox," Harold M. Griffith, Johnstown Ophthalmology for the General Practitioner, Leo H. Crip, Pittsburgh "Management of the Allergic Patient," Zoe A. Johnston, Pittsburgh, "Radium and X-Ray Therapy in the Treatment of Malignant Diseases," Elliott B. Lide, Uniontown "The Eye in Medical Diagnosis," and Bernard J. McCloskey, Johnstown, "Noninflammatory Diseases of the Appendix." Dr Louis Hamman, Baltimore, conducted a medical clinic and Dr John C. Hirst, Philadelphia a surgical clinic in the afternoon. At a dinner meeting at the Latrobe Country Club Dr Hamman and Dr Hirst gave addresses.

Philadelphia

Personal—Dr Frederick D. Weidman was recently made a corresponding member of the Austrian Dermatologic Society—Dr Joseph McFarland, professor of pathology in the University of Pennsylvania School of Medicine retired June 30 having reached the age limit. He remains as professor of pathology in the Evans Dental Institute and the Veterinary Medical School of the University.

Promotions at Jefferson College—The following promotions in the faculty of Jefferson Medical College have been made during the year just passed:

Dr John B. Flick to be associate professor of surgery
Dr Henry K. Mohler associate professor of therapeutics
Dr Lewis C. Scheffey associate professor of gynecology
Dr Henry K. Seelaus assistant professor of surgery
Dr Harold L. Stewart assistant professor of pathology
Dr David R. Morgan assistant professor of pathology
Dr Adolph A. Watling assistant professor of surgery
Dr William H. Schmidt, assistant professor of physical therapy in the department of neurology

Dr David M. Davis, formerly of Phoenix, Ariz., was appointed professor of genito-urinary surgery during the year.

Pittsburgh

University News—The University of Pittsburgh School of Medicine conducted its annual clinic for the graduating class alumni and members of the medical profession, May 23. The guest speaker was Dr John N. Hayes, Saranac Lake, on "Some Recent Tendencies in the Treatment of Tuberculosis." Dr Irvin D. Metzger, chairman of the state board of medical education and licensure, received the honorary degree of doctor of science at the commencement exercises, June 10. Dr Rutherford T. Johnstone has recently resigned as assistant professor of medicine, having removed to Los Angeles to live.

RHODE ISLAND

State Medical Election—Dr Walter C. Rocheleau, Woonsocket, was named president-elect of the Rhode Island Medical Society at the annual meeting, June 3, and Dr Guy W. Wells, Providence, secretary. Dr John E. Donley, Providence, was installed as president. The next meeting of the society will be in Providence.

TENNESSEE

Institute on Malaria Control—The Tennessee Department of Health sponsored an institute on malaria control at Jackson, May 26. Among the speakers were Drs Eugene L. Bishop, Knoxville, director of health for the Tennessee Valley Authority, who discussed "The Malaria Problem in Tennessee and the Surrounding Area," Henry E. Meleney, Nashville, "Medical Preventive Measures," Robert B. Watson, Wilson Dam, Ala., "Epidemiology of Malaria," Robert C. Derivaux, Nashville "Medical Curative Measures."

Tennessee Valley Meeting—Dr Edward A. Guynes, Knoxville was chosen president-elect of the Tennessee Valley Medical Association at the second annual meeting in Knoxville, June 10-12, and Dr Tom R. Barry, Knoxville was installed as president. Speakers on the scientific program included:

Dr James S. McEster, Birmingham, Common Forms of Nutritive Failure
Dr Raymond A. Vonderlehr, U. S. Public Health Service, Washington, D. C., Public Health Aspects of Syphilis
Dr Chauncey C. Maher, Chicago, Hypertensive Vascular Disease
Dr Leon Herman, Philadelphia, Obstructive Lesions of the Upper Urinary Tract
Dr Hayes E. Martin, New York, Curability of Intra-Oral Cancer by Modern Therapeutic Methods
Dr Walter C. Alvarez, Rochester, Minn., Helpful Hints in Diagnosing Gastrointestinal Disease
Dr Austin A. Hayden, Chicago, The Problem of the Hard of Hearing Patient

Dr Morris Fishbein, Chicago, editor of THE JOURNAL, gave an address at the banquet Thursday evening, June 11.

TEXAS

State Medical Election—Dr Calvin R. Hannali, Dallas was chosen president-elect of the State Medical Association of Texas at the annual session in Houston May 27, and Dr Howard R. Dudgeon, Waco, was installed as president. Vice presidents elected were Drs Wilburn C. Williams, San Marcos, Samuel D. Whitten, Greenville, and R. Spencer Wood, Waco. The next session will be held in Fort Worth.

Health at El Paso—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million indicate that for the week ended June 20 the highest mortality rate (206) appears for El Paso, the rate for the group of cities as a whole being 108. The rate for El Paso for the corresponding period last year was 139 and for the group of cities 109. The annual rate for eighty-six cities was 13 for the twenty-five weeks of 1936 as against a rate of 12.3 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have large Negro populations may tend to increase the death rate.

GENERAL

Diploma Stolen—Dr Jerome Matthew Brosnan, Chicago reports that his diploma from Loyola University School of Medicine disappeared from his room in the Little Company of Mary Hospital the day following graduation, June 11.

Winners in Rural Health Contest—Winning counties in the second annual interchapter rural health conservation contest conducted by the United States Chamber of Commerce and the American Public Health Association, were Westchester County, N. Y. northern division; Davidson County, Tenn., eastern division; Shawnee County, Kan., north central division; El Paso County, Texas, south central division; Glynn County, Ga., southeastern division; and Santa Barbara County, Calif., western division. The contest was limited to counties and districts having full time health services, of which 160 enrolled. Expenses of the contest were borne by the W. K. Kellogg Foundation, Battle Creek, Mich.

Conference on College Hygiene—Announcement is made of the Second National Conference on College Hygiene, to be held at the Wardman Park Hotel, Washington, D. C., December 28-31, under the joint sponsorship of the American Student Health Association, the National Health Council and the Presidents' Committee of Fifty on College Hygiene. The first conference, called by the same sponsors, was held at Syracuse University, Syracuse, N. Y., in 1931. There will be no formal program with prepared addresses. The work will be divided into five sections: health service, health teaching, organization and correlation, special problems and relationship of college hygiene to teacher training and secondary education. Dr Livingston Farrand, president of Cornell University, Ithaca, N. Y., is chairman of the conference and Dr William F. Snow, New York, is chairman of the organizing committee. Dr Hugh S.

Cumming, former surgeon general of the U S Public Health Service, is chairman of the Washington committee on arrangements. The executive office is at Room 828, 50 West Fiftyeth Street, New York, with Miss Louise Strachan as secretary.

Pacific Northwest Medical Association—The fifteenth annual meeting of the Pacific Northwest Medical Association will be held in Portland, Ore., July 8-11. Guest speakers will be

Dr. Lewis J. Pollock, Chicago, Epilepsy, Differential Nervous System Diseases.

Dr. Chevalier Jackson, Philadelphia, Cancer of the Larynx, Bronchospasm in Diagnosis and Treatment of Diseases of the Lung.

Dr. Ray M. Balyeat, Oklahoma City, Gastro-intestinal Allergy, Allergic Problems in General Practice, Intractable Asthma.

Dr. Carl Henry Davis, Milwaukee, Prophylactic Treatment of Thyroid Disease, Diseases of the Cervix Uteri.

Dr. David J. Davis, Chicago, Streptococcus Infections, Principles and Pathogenesis of Diseases of the Respiratory Tract, Pulmonary Abscess and Gangrene.

Dr. Paul J. Hanzlik, San Francisco, Vasomotor Tissue Extracts in Circulatory Disease, Diuretic and Antiedemic Drugs, Bismuth in the Treatment of Syphilis.

Walter J. Meek, Ph.D., Madison, Wis., Physiologic Background of Heart Diseases, Traumatic Shock, Beginning of American Physiology.

Dr. Alexis F. Hartmann, St. Louis, Vomiting in the New Born, Acidosis and Alkalosis, Otitis Media and Complications.

Dr. Russell L. Cecil, New York, Pneumonia, Arthritis, Influenza and the Common Cold.

Dr. Cyrus C. Sturgis, Ann Arbor, Mich., Physiology of Blood in Relation to the Anemias, Diseases Associated with Abnormalities of White Blood Cells, Periodic Loss of Consciousness.

Dr. Roy D. McClure, Detroit, Artificial Fever Therapy, Goiter and Iodized Salt Burns—Tannic Acid Treatment.

Dr. Harry E. Mock, Chicago, Surgical Conditions of the Alimentary Tract, Reconstructive Surgery, Craniocerebral Injuries.

American Association of History of Medicine—

Dr. Henry L. Sigerist, Baltimore, was chosen president of the American Association of the History of Medicine at its annual meeting in Atlantic City, May 4. Dr. Esmond R. Long, Philadelphia, vice president, and Dr. Edward J. G. Beardsley, Philadelphia, speakers included the following physicians:

Dr. Joseph H. Pratt, Boston, John Warren, the Father of the Harvard Medical School.

Dr. Edwin Robert Wiese, Philadelphia, The Status and Practice of Medicine in Imperial Rome.

Dr. Long, Concepts of Cardiac Pathology Before Morgagni.

Dr. Sanford V. Larkey, Baltimore, Children and Witches.

Dr. Michael L. Ravitch, New York, Dr. Pirogoff, the Russian John Hunter.

Dr. John R. Oliver, Baltimore, Spontaneous Combustion, a Literary Curiosity.

Dr. Louis H. Clerf, Philadelphia, Historical Notes on Foreign Bodies in the Food and Air Passages.

Ludwig Edelstein, Ph.D., Baltimore, Greek Medicine in Its Relation to Religion.

Dr. Robert H. Halsey, New York, The Correspondence Between President Jefferson and Dr. Waterhouse and Its Bearing on the Introduction of Smallpox Vaccination.

Dr. Owsei Temkin, Baltimore, Haller's Scientific Controversies.

The dinner session was addressed by Dr. Edward B. Krumpholtz, Philadelphia, on "Notes and Impressions of the Tenth International Congress held in Madrid in September 1935", Dr. Sigerist, "The Social History of Medicine," and Dr. Howard Dittrick, Cleveland, "Some Old Hospitals in Spain," illustrated.

FOREIGN

Society News—The sixth session of the "International Office of Documentation of Military Medicine" will be held in Geneva, Switzerland, October 12-14. All officers of the military medical services are invited. Those who wish to attend are requested to notify Dr. Voncken, director of the organization, Liege, Belgium, before September 1.—The annual meeting of the International Society of Medical Hydrology will be held in Austria, October 10-16, opening at Innsbruck. The party will proceed to Badgastein and from there to Salzburg. The subjects for discussion are "Spa Treatment of Disorders of Old Age" and "Radioactivity in Medicinal Waters." Full details may be obtained from the General Secretary, International Society of Medical Hydrology, 109 Kingsway, London, W C 2.

Society to Promote Electrotherapy—The Duchenne Society was recently organized in England to promote the ethical and rational use of electrotherapy. Members are Prof. Walter J. Turrell, Oxford, Sir Morton W. Smart, Drs. Elkan P. Cumberbatch, C. A. Robinson, Francis Howard Humphris and Philippe Bauwens. Lord Horder was elected medical consultant, Prof. Jean d'Arsonval, Paris, and Dr. Norman E. Titus, New York, foreign honorary consultants for France and the United States, respectively.

Congress of Otorhinolaryngology—The third International Otorhinolaryngological Congress will be held in Berlin August 17-22. Subjects to be discussed are radiotherapy of malignant tumors of the nose and throat, electro-auditory apparatus for aids to hearing and for examination of the hear-

ing, and influence of constitution on disorders of the ear, nose and throat. Those wishing to participate are requested to send their registration by August 1. The secretary general of the congress is Dr. Klaus Vogel, Berlin NW 7, Luisenstrasse 11-13.

Government Services

Changes in Public Health Service

Dr. Robert Olesen, medical director, U S Public Health Service, has been detailed as assistant surgeon general in charge of the division of sanitary reports and statistics, effective June 1. He succeeds Dr. Ralph C. Williams, who has been relieved as assistant surgeon general and assigned to duty as medical director of the rural resettlement administration with headquarters in Washington, D. C. Dr. Roscoe R. Spencer, senior surgeon, has been directed to report for duty in the division of sanitary reports and statistics. Surg. Calvin C. Applewhite has been relieved from duty as regional consultant for the New England district and directed to Chicago to assume charge as regional consultant for district number 3, succeeding Dr. Knox E. Miller. Dr. Carroll E. Palmer has been appointed and commissioned as passed assistant surgeon in the regular corps of the public health service.

Second Year Internships Available in Public Health Service

The U S Public Health Service announces that applications for second year internships will be received from physicians not over 30 years old who have graduated from class A medical colleges and who will have completed one year's internship at an approved hospital following graduation. It is especially desired to receive applications from candidates interested in the service as a career. No written examination is required. Candidates appointed for duty at Marine Hospitals and U S Narcotic Farms will receive a gross pay of \$1,800 a year from which a deduction of \$690 a year will be made if quarters, subsistence and laundry are furnished. Those assigned to the federal penal and correctional institutions will receive \$1,620 a year, from which \$240 will be deducted if quarters, subsistence and laundry are furnished. When quarters are furnished they cannot be shared by the interns dependents. Appointments will be made with the understanding that those appointed will have opportunity to take the next examination for appointment as assistant surgeon in the regular corps. Persons desiring to make application should communicate at once with the Surgeon General, U S Public Health Service, Washington, D. C., stating definitely that they are interested in a second year internship.

March a Record Month for Food and Drug Administration

Foods damaged by floods in the Eastern states brought a problem to federal and local officials during March, the Food and Drug Administration reports. Much of the damaged food was destroyed on the spot. Foods in transit or shipped in a damaged condition immediately after the floods were followed up by federal agents. Local officials in twenty-two cities report the destruction of 390 tons of fresh fruits and vegetables, coffee, tea, candy, cereals, flour, beans, dessert preparations, meats, shortenings, butter, dried fruits and nuts, spices and drugs. This does not include hundreds of small lots, in Pittsburgh, where damage was enormous, no estimate of condemned foodstuffs was attempted. Actions under the federal law to date have included seizures of 580,900 pounds of sacked feeds, 25 tons of corn, 200 bags of unroasted coffee, 11,410 pounds of coffee and one shipment of candy. Aside from the flood emergency, the administration reports the largest seizure month on record. Most important of the seizures was the result of a campaign to stop adulteration of olive oil, most of which was done in Massachusetts and New York. Nearly 49,000 containers holding a total of 11,255 gallons of olive oil adulterated with tea seed oil, most of it to the extent of 70 per cent, were seized. Second on the list in point of quantity seized were preserves deficient in fruit, of which 10,000 jars were confiscated. Mislabelled foods, grossly contaminated canned foods and shortweight packages made up the rest of the month's seizures. Dangerous drugs seized included a substandard pituitary solution, rubbing alcohol made up with isopropyl alcohol and an iodine compound. Numerous preparations labeled with cure-all claims were also included.

Foreign Letters

LONDON

(From Our Regular Correspondent)

MAY 16 1936

The International Congress of Physical Medicine

The sixth International Congress of Physical Medicine has been held in London. The honorary president, Lord Horder, was unable to attend owing to his previous acceptance of the invitation of the American Medical Association to attend the Kansas City session. Sir Robert Stanton Woods presided. In his presidential address, read by the honorary secretary Lord Horder said that it was the glory of medicine, like Bacon that it took all knowledge for its province. It was the child of all the sciences, and the best doctor was he who attached himself to no system and no sect but made use of every available piece of knowledge in the patient's interest. He welcomed the inclusion of a section of physical medicine in the medical schools. For many years he had urged its claims and he was gratified that its progress, which he predicted more than ten years ago had been amply fulfilled. The practice of physical medicine should be kept under scientific control, which could be achieved only by a close liaison between the physical therapist and the physician. The physical therapist should constantly realize that his approach must primarily be a clinical one. In proportion as he tended to isolate himself he lessened the benefits he could confer, for it was the patient and his reactions that constituted the official arbiter of results whether in diagnosis or in treatment, and it was the clinician who could best judge these.

PHYSICAL EDUCATION

Lord Dawson said that it was remarkable that the teaching of the golden age of Greece, with its ideal of equal training of body and of mind, should for centuries have disappeared. Denmark was the first modern country to make physical education an essential part of the curriculum of its schools. Ling whose system influenced physical education throughout the world soon followed. Great Britain had been the home of games and sports while continental countries were formulating their systems of gymnastics. Not until 1909 was physical education established in the elementary schools. He did not think that games could replace physical education. Proficiency in them was compatible with defects of frame or function, which might not make themselves felt until manhood, when they became a progressive handicap. Some games unless correlated with physical education, were liable to overstrain their votaries and impair health later in life. Equally physical education could not replace sport and games, for rivalry and the team spirit could not be derived from the former. Physical education was an increasing necessity in modern life. Formerly, when there were no organized social services to protect weak and damaged stocks, natural selection operated more effectively. Today they were preserved and it was the more necessary, therefore, to build them up. The physician, with his knowledge of the structure and functions of the body, should be associated with physical education. Early divergencies from normal development would thus be corrected at school.

THE HYGIENE OF SPORT

Sir Leonard Hill said that, in the well trained 20 or 30 per cent of the energy used in exercise was spent as work and the rest as heat, but any defect, such as sore feet or an ill balanced pack in the marching of a soldier or the crouching position of the miner, wastefully increased the energy output. Training brought about an enriched blood stream, a greater capacity for deep breathing, a building up of muscle, with loss of superfluous fat. Up to 18,000 feet Everest climbers improved, beyond that

oxygen want came into play and degeneration began. But with an oxygen breathing apparatus the climber could be made as efficient at 29,000 feet as at sea level. By breathing oxygen at the start of a race athletes had run the half or quarter mile within a second or two of their record runs. Breathing oxygen afterward prevented all leg stiffness and made them ready to run again. Sir Leonard Hill held that skilled movement was the basis of mental equipment. Yet 70 per cent of our youth between the ages of 14 and 18 did not participate adequately in physical training. At the universities, boys were promoted without due consideration of their physique.

The Prevention of Blindness

The Standing Committee on the Prevention of Blindness of the Union of Counties Associations for the Blind has presented an important report. The committee consists of ophthalmologists, health officers and others interested in the problem of the blind. They state that there is at the present day much blindness which might have been prevented if suitable precautions had been taken in time. There is also a definite number of cases in which some degree of useful sight can be restored by proper measures. These two factors led to the formation of the committee. In England the movement for prevention of blindness began about 1879. The London Society for the Prevention of Blindness was formed of which Dr. Roth was the honorary secretary. In a paper read at a conference in 1883 he enumerated four forms of ignorance as among the more important causes of blindness: (1) ignorance regarding ocular hygiene of mothers and nurses and all those to whom the care of children is entrusted; (2) ignorance of schoolmasters and school mistresses in matters of health and physical education; (3) ignorance and neglect of the working classes regarding influences affecting their general health and causing diseases of the eyes; (4) ignorance of many physicians with regard to eye diseases. This society did not survive long but it was the first organized movement for the prevention of blindness in this country.

In 1889 the Royal Commission on the Blind recommended that the intermarriage of the blind should be discouraged, that information on the treatment of purulent ophthalmia should be circulated by sanitary authorities or through the post office that school children with defective sight should be periodically examined and glasses ordered and that greater attention to ophthalmology should be encouraged among physicians. In 1909 the notification of ophthalmia neonatorum was made compulsory. In 1923 the General Medical Council made the instruction in ophthalmology of every medical student compulsory. But the standing committee holds that the present arrangements do not secure that in general the physician has the requisite knowledge of ophthalmology and it considers that the matter should continue to receive the close attention of the curriculum committee of the General Medical Council.

The standing committees make a number of recommendations. It is essential that squint and amblyopia associated with it should be treated as early as possible. Improvement in children's surroundings and early treatment, particularly in open air schools would markedly reduce the ravages of phlyctenular disease. Sympathetic ophthalmia must still be reckoned with as a serious danger, especially when a foreign body has perforated the eye and is retained within the globe or when it is known that the ciliary region has been affected. The outlook is always serious and it still seems necessary to emphasize the importance of removing immediately an eye so seriously injured that there is no possibility of useful sight. Glaucoma proceeds so insidiously that it may pass unnoticed for years unless the eyes are properly examined. The patient may think it is only a matter of buying stronger glasses and may so obtain temporary improvement in sight yet the field of vision may be

slowly contracting with less hope from subsequent operation. A comprehensive and adequate system of interpartum supervision is important as a means of safeguarding the sight of both mother and child. A hospital should be maintained with the centers for the treatment of venereal disease. Ophthalmia neonatorum requires such constant attention and such skilled nursing that it is best treated in a hospital. For prophylaxis the use of 1 per cent silver nitrate should be included in the training of every midwife. The visual conditions of children should be examined as soon as possible after entry into school. As myopia may seriously progress in adolescence supervision by the ophthalmologist after leaving school may diminish the risk of subsequent blindness. The greatest risk of occupational blindness occurs in metal working, from splashing in chemical processes and in stone dressing. The eyes should be protected by goggles or a screen fixed to the machine. The risk to the eye is particularly heavy in coal mines and in quarries raising igneous rock. Proper medical attention should be sought immediately after all eye injuries, as those which may seem trivial may turn out to be serious.

Gift for Research to the Cavendish Laboratory

Sir Herbert Austin, the automobile manufacturer, has made the munificent gift of \$1,250,000 to the famous Cavendish laboratory at Cambridge University. In acknowledging it the director Lord Rutherford, says that it will give an opportunity of building a modern research laboratory and will also be of great value in helping to defray the large expenditure required for modern research in physics. The first use of the money will be to build a laboratory for the utilization of very high voltages, in order to carry out experiments on the transmutation of matter by high speed particles and by radiation.

The laboratory perpetuates the name of one of the greatest experimenters, Henry Cavendish who discovered the composition of water. The successive directors bear names too great for any praise—Clerk Maxwell, Lord Rayleigh, Sir J. J. Thomson, Lord Rutherford. Among the advances made in the laboratory was the discovery of the electron in 1897 and of the neutron in 1932. Of remarkable apparatus in use there may be mentioned Prof. C. T. R. Wilson's cloud chamber, in which the tracks of atomic particles have been photographed, and Dr. F. W. Aston's mass spectrograph, by which individual atoms can be weighed.

Medical Refugees in England

In the house of commons it was officially stated in reply to a question that since March 1935 refugees who have applied for permission to reside in this country for the purpose of medical study have been informed that permission can be granted only on the understanding that after qualifying they will not establish themselves in practice in the United Kingdom but will leave the country. However, among the refugee physicians who came before that date 148 have been granted permission to practice after they have obtained a British medical qualification. This permission has been granted on various special grounds. In some cases of eminent physicians having special attainments their colleagues in this country have asked that they be allowed to practice here.

Karl Pearson

By the death of Prof. Karl Pearson in his eightieth year is removed a man who was not a physician but who rendered unique service to medicine by placing its statistical methods on a scientific basis. A mathematician with a distinguished university career, he was appointed to the chair of applied mathematics at University College, London. He was early attracted by the work of another great pioneer, Francis Galton, a cousin of Charles Darwin and the founder of the science of

human heredity. His books on "Hereditary Genius" and "Noteworthy Families" are well known. His investigations brought him up against the fundamental principles of statistics, for which his mathematical knowledge was insufficient. Pearson supplied the deficiency. Galton originated the science of eugenics, to which he gave that name. He founded the chair of eugenics at University College by the munificent endowment of \$225,000 and, according to his wish, Pearson became the first professor. He was also director of the Galton Laboratory of Eugenics at the same college. With the approval and support of Galton he founded the journal *Biometrika*. He was editor of the *Annals of Eugenics*. He gathered round him a number of pupils who became distinguished later. Among these may be mentioned L. N. G. Filon, F.R.S., recently vice-chancellor of the University of London, Prof. Major Greenwood, F.R.S., a well known authority on vital statistics, and Prof. Raymond Pearl of Johns Hopkins University. It was Pearson who taught medical writers how to use statistics scientifically. At first his criticisms of their methods aroused much opposition, but he prevailed in the end. The extent of his activities was enormous, they ranged over pure mathematics, mathematical statistics, philosophy, history, anthropology and eugenics.

May 15 1936

Complication Following Treatment with Gold Salts

A warning about the treatment of pulmonary tuberculosis with gold salts was sounded by E. Bernard and M. Morin at the Société médicale des hôpitaux of Paris, March 20. A woman, aged 27, had been ill since May 1935. Radiography in July of that year revealed a tuberculous cavity in the left upper lobe, and tubercle bacilli were found in the sputum. A pneumothorax treatment having been unsuccessful, a phrenicectomy was performed July 20, and administration of gold salts begun. The total dose given up to October 4, a period of ten weeks, was 4.05 Gm. Signs of stomatitis then appeared. The neurologic symptoms appeared October 10 in the form of almost intolerable pains of a lancinating character in the right arm and leg, accompanied by bilateral muscular fibrillation. Psychic disturbances took the form of restlessness, insomnia and the desire to commit suicide, at the end of the series of injections, and were due to the gold salts alone, because all other causes of toxemia could be excluded. The total dose given could not be considered toxic, but in the case of gold salts, as in the administration of the salts of arsenic, the complications do not appear after a single or several injections but at the end of the treatment. It would appear as if the metal had a special affinity for certain tissues. Similar cases have been reported by a number of authors, in which all four extremities (Gernez), both legs (Beyerholm, Alajouanine, Berthier), both arms (Lambea) or only one limb (Jzanck) was involved.

Stomatitis Due to Administration of Gold Salts

At the March 27 meeting of the Société médicale des hôpitaux of Paris, Charles Flandin and his associates reported two cases of severe stomatitis following the use of gold salts. As a rule, the stomatitis develops rapidly and is relatively benign, recovery taking place after a short interval. Even when ulceration occurs, it is exceptional for healing to require more than a month. In addition to this acute form, the stomatitis may develop slowly, as in the two cases observed by Flandin and associates. In one of these, 18 Gm. of a gold salt was given over a period of seven weeks for an acute pulmonary congestion in a man aged 49, the examination of whose expectoration had revealed, twelve years previously, the presence of tubercle bacilli. The gold salt therapy had been followed by a lichen-like cuta-

neous eruption and a subacute stomatitis, which was of seven months' duration when the patient was first seen by Flandin. In the second case, a psoriasis which had resisted all treatment was treated by 7 cc of a suspension in oil of a gold salt. This was followed by the appearance of an acute colitis and ulcerative stomatitis, which became subacute four months after the onset. The colitis persisted for more than a year. The stomatitis in the form of recurrent superficial erosions persisted for two years. Clinically this chronic type resembles closely the more benign acute form, but the former differs from the latter in being resistant to all local and general treatment as long as the gold salt treatment is continued.

Flandin stated that this stomatitis, when considered in conjunction with others previously reported, should lead one to be cautious in using gold salts, especially in view of the fact that the efficacy of the treatment in pulmonary tuberculosis is questionable.

Relation of Gastric and Duodenal Ulcers to Appendicitis

At the March 20 meeting of the Société médicale des hôpitaux of Paris Charles Flandin reported a case in which persistent gastric symptoms had been present during the preceding two years. A diagnosis had been made of chronic appendicitis with accompanying gastric symptoms. The clinical picture was that of an acute appendicitis but the possibility of the perforation of a gastric ulcer was kept in mind because the pain at the onset had been in the gastric region. An emergency operation performed three hours after the onset revealed a large appendix, nonperforated but filled with yellowish pus and a fecalith. When the peritoneal cavity over the appendix region was opened, a brownish mucoid fluid escaped, hence in the absence of a perforated appendix an exploration of the stomach and duodenum was indicated. This revealed the perforation of a gastric ulcer in the prepyloric area. Recovery was uneventful. Flandin was of the opinion that the removal of the appendix should have been done when the diagnosis of chronic appendicitis was made two years previously to avoid gastric complications.

In the second paper, Brodin and Tedesco stated that the frequency with which appendicitis and ulcer of the stomach or duodenum has been observed indicates that a causal relation exists between the two conditions. Either they have a common etiology or the presence of one favors the development of the other. The authors believed that the focus in the appendix was the primary one and that the infection reaches the gastroduodenal region by way of the lymphatics of the ileocecal angle. The lymphatics from the appendix cross the third portion of the duodenum with the mesenteric vessels as Braithwaite, Basset and Beule have shown. An inflammation of these lymphatics gives rise to a spasm of this third portion of the duodenum with resultant proximal stasis and alteration of the chemical constituents of the duodenal contents.

A case illustrating a correlation of an appendicitis and duodenal ulcer was cited by Brodin and Tedesco. A man, aged 33, had recurrent attacks of appendicitis over a period of eighteen months. About three years after an appendectomy, three attacks of pain over the gastric region accompanied by vomiting occurred during the following three years. Radiography revealed a dilated duodenum. At operation, in addition to this condition, adhesions were found at the duodenojejunal junction. About thirteen months later, several severe hemorrhages occurred, which had their origin in a duodenal ulcer, as shown at a second operation. The authors are of the opinion that, if evidence of duodenal retention due to spasm in its third portion is found in a patient with appendicitis, early operation is indicated to avoid gastric or duodenal ulcer.

Acute Dilatation of Stomach Following Artificial Pneumothorax

Although this condition is well known as a postoperative complication, and following severe abdominal injuries (not operated on), its occurrence as an accompaniment of certain nonsurgical lesions is not yet well known.

Jacob and Dupuy reported a case at the March 13 meeting of the Société médicale des hôpitaux of Paris of acute gastric dilatation after thoracentesis to relieve pressure symptoms after an artificial pneumothorax. A woman, aged 30, had been given nine insufflations of air into the pleural cavity as part of the treatment of a right-sided pulmonary tuberculosis. The last treatment was given May 6, 1935. Four days later, symptoms of a severe pleural reaction appeared with displacement, by exudate and air of the mediastinum toward the left side of the thorax. Decompression was done May 22 by aspiration of 325 cc of air from the right pleural cavity. On the same day and for several days following this procedure, the patient vomited large quantities of bile stained fluid without effort, a symptom often seen in acute gastric dilatation. After repeated gastric lavage supplemented by the administration of large amounts of saline solutions, the vomiting ceased. The sudden onset of the symptoms of acute gastric dilatation after the thoracentesis was due to reflex inhibition of the musculature of the stomach, in the opinion of Jacob and Dupuy. They cited a similar case of Papouk, following internal urethrotomy for stricture. The acute gastric dilatation symptoms appeared half an hour after the intervention.

May 6, 1936.

News of the Student Bodies

Since the last report on the faculties and student bodies of German universities (*THE JOURNAL*, Dec. 7, 1935, p. 1926), several changes have taken place. The maximal numbers of students allocated to the various universities have again under gone slight reduction for most of the institutions, and (what is illuminating and characteristic) this has been done "in consideration of the anticipated decline in the student population."

Rumors, all officially denied, have had it that several universities or departments of universities were to be suspended. It was first reported that Frankfurt-on-the-Main was the school in question, later, similar rumors were circulated with regard to the Universities of Halle, Giessen and Cologne.

The number of preferred categories of candidates for admission has been augmented to include persons belonging to such National Socialist organizations as the SA [Sturm Abteilung] and the SS [Schutzstaffel] (both well known older party groups), the Hitler Youth and the League of German Girls (that is the two young people's organizations) and the Nazi Motor Corps. Also considered eligible for admission are students who have completed two semesters' study in a nonquota (a less important) university and who intend to return later to their original institutions. On the other hand the rector of a university may investigate the status of those students who have studied for longer than three semesters in a quota university.

The National Socialist studentenbund has recently pledged itself to bring the entire student body of the German universities within the membership of one or the other of the foregoing party organizations. All members or prospective members of the studentenbund have until May 1 to apply for membership in one of the foregoing Nazi organizations. Studentenbund members are in addition divided into "kameradschaften" of some thirty men each, and further there are the "stamm-mannschaften" (nuclear groups) of from thirty to sixty men each, according to the size of the university. The latter

must be politically tried and true students "who have already proved their National Socialist zeal for cooperative activity" Beginning with the next winter semester, the studentenbund will endeavor "to bring the developmental influence of the kameradschaft to all first to third semester students" Thus the National Socialist studentenbund is in a fair way to achieve complete and forceful subjection of entire student bodies to the Nazi program of indoctrination

Two years ago a similar but unsuccessful attempt was made by the studentenbund to assume control of the club houses belonging to the old corps and other student societies and convert them into "kameradschaft houses" This offensive has now been renewed but with greater force Admission to the studentenbund too has now been made more difficult New members can be taken in only by special selection Formerly the bund sought the largest possible membership but its recruiting activities gathered in only a mediocre harvest (it is estimated that today about one third of the entire student body are bund members) So now the bund has reversed itself and adopted a policy of exclusiveness Only a limited number of students may be full members" of the bund, while, on the other hand, its program of 'complete indoctrination' includes the entire student body The sturmtrupp forms a sort of hierarchy which is expected to produce leaders

By this latest offensive the last vestiges of individual freedom of action among the present generation of students has been swept away In addition, it serves further to break the hold of the church on Roman Catholic students, since within the past year the Catholic student organizations have been disbanded

Only recently reichsminister of public instruction Rust complained that the universities still failed to present a picture of complete integration within the National Socialist movement 'The nearer we approach the center of the old forces" said Rust, 'the tougher appears the stuff of which they are made So many difficulties beset the path to a complete intellectual transformation because so many men in the sphere of science and research are absolutely incapable of changing their ideology" Much that lives on in the academic realm is of yesterday and before yesterday And the tragic part of it is that these forces of reaction are not yet opposed by a student body united in purpose. This fact (and here is a noteworthy utterance) must not be attributed to a lack of essential weltanschauung on the part of the students but rather to a certain sluggish reluctance to participate in cooperative action The fight to be carried on in the universities is the struggle of the party

Thus harsh words are rained on the universities from the highest governmental quarters The National Socialist studentenbund, as its leader recently explained, wishes to end this procrastination once and for all No more compromises" is the group's new slogan The complete suppression of the old student corporations or corps has not yet been effected despite all the previous efforts of a bund openly backed by the national government The Kösener SC and other federations of the old fraternities were hastily disbanded last autumn, but on the other hand the individual corps in the various university towns have refused to disband in the face of repeated exhortations and appeals Each corps has been existing on its own without any organized liaison

A further development was the recent prohibition of simultaneous membership in a corporation and the National Socialist studentenbund, the latter group thus taking the simplest and most expeditious way out of the impasse The burschenschaften have gone over to the bund in larger numbers, notably at Bonn and at Marburg, where the student fraternities were formerly extremely prominent Only one burschenschaft remains, which still conducts its activities in the old manner

The proceedings of a district convention of the studentenbund held in February at Cologne give a good idea of what the new type of German student will be like Before this gathering the national führer of the studentenbund, Derichsweiler, dedicated a number of flags while a speaking chorus recited "May the banners of victory wave and may foul things vanish before them" In the front rank of the foul or decayed things referred to are the student corps

The Nazi education of the student has yet another mission "It must teach him sternly to oppose much that is expounded from the professorial chair—not that we intend to set up a supplementary body of learning—but that which is taught should have its roots in National Socialist doctrine And we (students of the bund) will not hesitate to stamp on the floor and whistle in the lecture room should the instruction fall short of this standard" Such were the words of the official leader of the National Socialist studentenbund

The state examinations offer a candidate the best opportunity for demonstrating his learning Now, however, emphasis is being placed on personal deportment rather than on scholarship The basic evaluations made of a student by all the Nazi organizations with which he comes in contact may well be of far-reaching effect Under this system youthful peccadillos may be scored up against the individual for the rest of his life and a record of his misdeeds hover over him like a modern sword of Damocles The concluding remarks of the führer of students may be quoted as characteristic "The responsibility that we bear is enormous It rests with each one of you whether or not in future any educator from the rector of a university to the village schoolmaster shall be a reactionary The responsibility is now ours Our organization of young men has gotten its stride. Those of us who attended the bund's decennial celebration at Munich were filled with enthusiasm but at the same time with fierce anger against those men who believe that their heyday will come again and that they like phoenix, shall arise from the ashes For the time dear to those who live in their yesterdays shall never return"

Selection of Healthy Students

As early as March of last year the minister of education issued regulations to govern admission to the gymnasiums It was stipulated that youths having permanent disabilities serious enough to impair their vital powers as well as those deemed to be carriers of hereditary disease should be excluded from the secondary schools, further, that a young person who exhibits a habitual aversion to bodily cleanliness and who shows no disposition to overcome this fault shall be subject to expulsion from the secondary schools Similarly, continued failure in physical education, above all if accompanied by an unwillingness to harden one's body and to participate in gymnastic and athletic activities, leads to expulsion unless the school physician and the instructor in physical education concur in a recommendation that the pupil be allowed to remain

Recently, supplementary regulations have been issued on the part of the reichsminister of the interior The medical officers who make the official examinations are to be guided by the following considerations All youths presenting physical and mental defects which preclude the successful preparation for and practice of a profession must be classed as unconditionally unfit for admission to the secondary schools Among such disqualifying defects are cardiac dysfunction with bad decompensation, severe asthma with persisting organic alterations, serious chronic kidney complaints, visual disturbances in which capacity is less than one third of normal or in which deterioration is to be anticipated, deaf-mutism, deafness and disorders of hearing equivalent to deafness, speech defects due to cleft palate, serious organic nervous and cerebral diseases, and dis-

cases of the endocrine system which are deemed incurable and which are accompanied by alterations of the intelligence and personality or tend to become progressive. In the latter category belong secondary encephalitic conditions, multiple sclerosis, Thomsen's disease, Friedrich's ataxia, syringomyelia, progressive muscular atrophy, myxedema and severe traumatic epilepsy. Further may be mentioned psychic disturbances as well as medically established feeble-mindedness of low grade. Moral defects are especially to be noted among the feeble-minded. Admission may be refused in cases of epilepsy marked by severe and frequent fits or accompanied by loss of intelligence and modifications of personality, manic depressive insanity in severer forms, serious psychopathic states especially constitutional instability, sexual degeneracy, drug addictions, and severe manifestations of hysteria.

Classed as temporarily unfit are youths with infectious diseases, disturbances such as chorea minor which lend themselves readily to imitation, petit mal, psychoses of toxic or infectious origin, and so on.

Hygienic and Political Considerations in Selecting Students

The reichsminister of education has just issued regulations with regard to hygienic and political considerations in the selection of university students. Selection is to be based on the results of official examinations which are to be carried out during the first and fifth semesters in cooperation with the Bureau of Public Health of the National Socialist Party.

"Unconditionally unfit" corresponds somewhat to the same term as applied to candidates for admission to the secondary schools. Carriers of hereditary disease are here similarly refused admission and expulsion for reluctance to acquire physical hardihood by participation in physical exercise is also provided for. As conditionally unfit are classed those students whose physical and mental powers are so seriously impaired that the completion of a professional course and later successful pursuit of a career are problematic. Such candidates may be excluded from study.

This health service is financed by the obligatory contributions of the students and it is able to offer as detailed recommendations as any specializing clinic. An appeal may be taken from the decisions of the rector or the resident commission to the minister of education.

Prognosis in Tuberculosis of the Larynx

Dr Arold discussed before the Giessen Medical Society the investigations conducted a few years ago by the newly erected Seltersberg Sanatorium. In the first two years of the sanatorium's existence it was possible to observe 157 patients with pulmonary and laryngeal tuberculosis. Of these 157 cases, forty-five ended fatally at the sanatorium. The 112 survivors were classified according to condition at time of discharge as follows: clinically healed larynx, thirty-six, considerable improvement, twenty-seven, indications of some improvement, fifteen, larynx condition deteriorated or unchanged, thirty-four. Four years subsequent to discharge from the sanatorium, fifty of these patients were ascertained to be living; thirteen could not be located and the remainder had died of severe progressive pulmonary tuberculosis. Follow-up examination of the fifty disclosed that in forty-eight the laryngeal disease had remained cured. Pulmonary examination of the latter number gave negative results in only twenty-five while in the other twenty-three the pulmonary disease had advanced since discharge from Seltersberg. Records also showed that in several of the group who had died of pulmonary tuberculosis in the interim the larynx had remained free from the disease to the end. Permanent cure of the laryngeal condition took place both in cases involving limited laryngeal processes and those in which

the area of involvement was more extensive. All these data evidence that prognosis in tuberculosis of the larynx depends not only on a tendency of the pulmonary processes to spread or on extension of the local process but also on the efficient carrying out of proper therapeutic measures.

Death of Prof. Hugo Sellheim

Dr Hugo Sellheim of Leipzig, professor of obstetrics and gynecology, died suddenly not long after his retirement from active service. He had reached the age of 65. One of the most illustrious pupils of Hegar, Sellheim, while still young, was appointed ordinarius at Tübingen. Thence he went to Halle and since 1926 had occupied the Leipzig post. Sellheim did effective work in virtually every sphere of his specialty. His principal contributions, however, had to do with the mechanism of labor and the protection of the mother.

Phrenicectomy in Pulmonary Tuberculosis

Dr B. Fleury de Oliveira, in the meeting of phthisiologists at the Associação Paulista de Medicina, January 23, read a preliminary report on the mechanism of action of phrenicectomy in pulmonary tuberculosis with lesions either at the apex or at the base. The speaker, based on the modern conceptions on the mechanics of respiration, especially those of Monaldi and Pirodi, says that phrenicectomy acts probably by the production of collapse if the lesions are located at the apex and by immobilization if they are located at the base of the lung. If these hypotheses were true different circulatory conditions would exist in the apex and in the base after performance of phrenicectomy, regardless of the cure of the lesions located either at the apex or at the base. According to the speaker, certain failures of phrenicectomy in lesions of the base of the lung could be explained by these theories. He believes that one of the conditions for the success of phrenicectomy in the presence of lesions of the base is the cutting of pleural adhesions.

Pan-American Congress of Tuberculosis

The Union Latino Americana das Sociedades de Tisiologia is composed of the antituberculous societies of Argentina, Brazil, Chile and Uruguay, each of which is represented by three advisers who are concerned with the organization of antituberculosis congresses. Advisers from Brazil are Drs. Antonio Cardoso Fontes and Ary Miranda of Rio de Janeiro and Clemente Ferreira of São Paulo. A congress of tuberculosis of the union has been recently organized, which will take place in the very near future. The medicosocial topic selected is "Organization of Crusades Against Tuberculosis in South America." Brazilian speakers on this topic are Drs. Marcos Antonio Nogueira Cardoso of São Paulo and Genesio Pitanga of Rio de Janeiro. The official topic for Brazil is "Diagnosis of Activity and Evolution of Pulmonary Tuberculosis." Speakers are Drs. Raphael Paula Souza, Antonio Tisi Netto and Fleury de Oliveira of São Paulo. Co-speakers are all members of the antituberculosis society of Rio de Janeiro.

Visceral Leishmaniasis

Dr Evandro Chagas recently reported a case of visceral leishmaniasis. A white boy, aged 16, a resident of Aracaju, Sergipe, became ill during a visit to Santa Maria, Rio Grande do Sul, a year and a half previously, simultaneously with his mother and sister, who died a few months later. In the necropsy of the sister it was found that the liver was heavily infested with *Leishmania*. The patient suffered from chills, fever, either intermittent or irregular, weakness, air hunger, nasal hemor-

ringes, diarrhea, progressive emaciation and darkening of the skin and dehydration of the tissues. At present the fever is irregular, oscillating from 98 to 100.4 F. Emaciation is extreme and the abdomen is of enormous size because of the presence of hepatomegaly and splenomegaly. Diarrhea appears in frequent crises but there is no blood in the feces. There are no nervous, circulatory, respiratory or urogenital disturbances. The physical development is retarded, while the mentality is normal. Leishmaniasis in large numbers, morphologically similar to *Leishmania Donovanii*, could be seen on the slides prepared with the blood of the patient's spleen taken by a puncture. Some of the parasites were free in the blood but the greater number of them were contained in macrophages. The peripheral blood picture is as follows: hemoglobin 44 per cent, erythrocytes 2,919,000, hematocrits 19, reticulocytes 4 per cent, white cells 2600. The percentage of monocytes was 34, lymphocytes 31, neutrophils 33, eosinophils 0 and basophils 0. *Phlebotomus Longipalpis* in great numbers was found at the city in which infestation of the patient occurred. This is the first clinical autochthonous case of kala-azar found in Brazil.

ITALY

(From Our Regular Correspondent)

April 22, 1936

Congress of Psychologists

The eighth National Congress of Italian Psychologists was recently held at Rome under the chairmanship of Prof. Cesare Colucci. Fourteen articles were presented, followed by illuminating discussions. Professor Colucci emphasized that the didactic material already compiled suffices to carry on investigations for evaluation of the mental capacity. His statement is based on results of personal investigations performed in industrial and municipal schools. All psychologists admit that the unitary conception of personality and the collaboration of experience prevails also in psychology.

Professor Della Valle said that the influence of psychology should be felt in the schools as well as in individual and collective relationships. Professor Bonaventura said that psychology is a science essential to childhood and that the orientations of mental hygiene should be applied to child life as early as during the nursing period, at which time many psychic reactions develop. The evaluation of the psychic reactions of infants constitutes a branch of science called nepiology.

Professor Puca emphasized that the actual separation of insane asylums and neurologic clinics has resulted in advancement of the study of psychology. The maintenance of close bonds between experimental psychology and pathology is advisable also for the interest of normal psychology.

Professor Gemelli, dean of the Università Cattolica of Milan, spoke on the task of psychology in the study of delinquency. Psychologists should be especially concerned with investigations of this nature. The president of the congress, based on his experience in reviewing records of criminals and of young delinquents in houses of correction of Naples, said that tendencies to crime can be inhibited or moderated by education.

Colonel Sarfatti, based on his war experience, spoke on the psychology of the order to attack. Professor Della Valle discussed this type of psychology from the point of view of the influence of suggestion by the commander and of the complicated mental processes concerned in the narrowing of consciousness to the single aim of those who advance to the attack with complete self sacrifice.

Professor Colucci emphasized the several experimental and scientific fields that are open to psychologists, in the interpretation of children's drawings, of manuscripts of recluses and the examination of artistic documents. The next congress of psychology will take place in Naples.

Society Reunion

The Società Piemontese di Chirurgia held a reunion during which Professors Chiarolanza and Segre spoke on calcaneal fractures. Professor Chiarolanza's experience covers more than eighty-five cases. More than 104 roentgenograms showing varieties of calcaneal fractures form the collection of the speaker. Fractures of the inferior aspect of the calcaneum and isolated fractures of the plantar tuberosity are rare. As a rule the fracture starts at the upper aspect of the calcaneum and as the fracture advances into the bone, one or more fractures are produced. At the operation many fractures are seen that were not seen in the roentgenograms. In more than 5,000 fractures treated in the Ospedale dei Pellegrini of Naples only thirteen were calcaneal fractures. The enlargement of the calcaneum, the lowering of the malleoli, the fall of the plantar vault and the presence of pericalcaneal extravasation are important diagnostic symptoms. The speaker treated his cases first by immobilization and then by physical therapy.

Meeting of Accademia dei Fisiocritici

The Accademia dei fisiocritici met recently in Siena, under the chairmanship of Professor Spirito. Professor Martinetti reported the results of his experiments on the action of intravenous injections of hypertonic dextrose solution on intracranial pressure as well as on retinal pressure. The injection is followed by transient increase of the intracranial pressure and then by a progressive lowering of it, which lasts from twelve to fourteen hours. The lowering of the retinal pressure following the injection is a valuable index for determining the vasodilatation of the cerebral arteries. The speaker believes that the results of his experiments point out the advisability of using hypertonic solutions for therapeutic purposes.

Professors D'Antona and Valensin spoke on the immunizing value of diphtheritic anatoxin. They concluded that anatoxin when prepared with nonfiltered toxins, containing therefore diphtheritic bacteria in suspension, has a higher immunizing power than that of ordinary anatoxin. The action of suspended bacteria in the anatoxin is identical with that of other non-specific substances which stimulate immunity by means of the production of local reactions.

Takata Test

Professor Dogliotti, in a lecture recently delivered before the members of the Accademia Medico-fisica of Florence, reported his results with the Takata test with the blood serum of more than 200 patients suffering from various diseases, especially liver diseases. The test gives intense positive results in cirrhosis of the liver. In other diseases (nephritis, hepatitis, pneumonia and cachexia) the test gives either negative or partially positive results.

Deaths

Prof. Cesare Biondi, professor of legal and industrial medicine at the University of Siena, recently died at Siena. Dr. Biondi had been a professor at the University of Sardinia and medicolegal adviser of the army during the war. At the time of his death he was a member of the permanent committee for the study of industrial diseases and accidents. He wrote important articles and books on self-inflicted injuries, evaluation of invalidism, and other industrial and social topics.

Professor Livierato, ordinarius at the Genoa University, recently died. He was the founder and provider of the Istituto Genovese di patologia medica dimostrativa propedeutica.

Dr. Guglielmo Romiti, professor emeritus of anatomy of the University of Pisa, is dead. He wrote several books on anatomy. Many professors of anatomy now teaching in Italian universities were his pupils. Romiti's teachings on anatomy have prevailed in Italy for the last half century.

Marriages

GORDON FREDERICK JACKSON, Toronto, Ont., Canada to Miss Kathryn Phillips of East Orange, N. J., in Lincolndale, N. Y., May 4

RALPH MILTON DE PASQUALE, Pelham Manor, N. Y. to Miss Lauretta Gertrude McCormick of Rochelle Park in May

MORTON MORRIS PINCKNEY, Richmond, Va., to Miss Louise Lippitt Sinnickson of Bryn Mawr, Pa., May 16

JAMES P. PREGNALL JR. Asbury Park, N. J., to Miss Marian Elizabeth Thompson of Allenhurst, May 12

JOHN CRAWFORD HOLMAN JR. Franklin, Texas, to Miss Margaret McKinzie of New Orleans, June 20

JOSEPH A. GILMARTIN, Pittsburgh, to Miss Genevieve D. Heyl of Elizabeth City, N. C., April 17

JOSEPH BERNARD BRAIN, Isabella, Pa., to Miss Mildred Marie Peters of Masontown, June 16

ABRAHAM I. RAMENOFKY, La Salle, Ill., to Miss Elizabeth Lantin of Los Angeles, June 7

LELAND COFFEY BROWN, Stuart's Draft, Va., to Miss Marjorie Mower of Staunton, April 18

HARRY M. MORGAN, Winlock, Wash., to Miss Ruth Reed of Nehalem, Ore., May 30

Deaths

Alfred James Ostheimer, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1898, served during the World War, formerly connected with the U. S. Public Health Service and the Veterans' Bureau, at one time medical director of the mental hygiene division of the Public Charities Association of Pennsylvania, aged 61, died, March 23, in the Veterans Administration Facility, Coatesville of coronary thrombosis

George Franklin Bauch, Lansing, Mich., Western Reserve University Medical Department, Cleveland 1892, University of Pennsylvania Department of Medicine, Philadelphia, 1894, member of the Michigan State Medical Society, past president of the Ingham County Medical Society, on the staff of the Edward W. Sparrow Hospital, aged 65, died April 5, of cerebral arteriosclerosis

Jesse Lee Paine & Olympia, Wash., Eclectic Medical College, Cincinnati, 1916, past president and secretary of the Thurston-Mason Counties Medical Society, formerly on the staff of St. Peter's Hospital, aged 48, died March 18, of an infection of the brain following a scratch on the nose inflicted by a prisoner

Vincent Alan Farrell & Mason City, Iowa, Northwestern University Medical School, Chicago, 1901, formerly on the staffs of St. Joseph's Mercy Hospital and the Story Hospital, aged 59, died suddenly, April 6, of embolism following an injury to the hip due to a fall

Thomas Edward McEvoy, Worcester, Mass., Yale University School of Medicine, New Haven, 1892, member of the Massachusetts Medical Society, aged 76, for many years on the staff of St. Vincent Hospital, where he died, March 28, of septicemia and diabetes mellitus

Virgil Harrison Danford & Wallum Lake, R. I. Ohio State University College of Medicine, Columbus, 1915 served during the World War, medical superintendent of the State Sanatorium, aged 47, died, April 21, in the University Hospital, Columbus, of coronary occlusion

Francis George Curtis & Ashfield, Mass., College of Physicians and Surgeons, Medical Department of Columbia College, New York 1883, for many years chairman of the board of health of Newton and on the staff of the Newton (Mass.) Hospital, aged 78, died April 7

Francis Scrimzeous Furman, Shreveport, La., Tulane University of Louisiana Medical Department, New Orleans, 1891, served during the World War, at one time member of the city board of health, aged 66, died, April 12, in a local sanatorium, of pneumonia

Fred Lee Bates, Lima, Ohio, Cincinnati College of Medicine and Surgery, 1889, for many years member and president of the board of education on the staffs of the Lima Memorial Hospital and St. Rita's Hospital, aged 69, died April 30, of cardiac decompensation

Robert Alexander McIlhenny, Conway Springs, Kan., Rush Medical College, Chicago, 1891, member of the Kansas Medical Society, past president of the Sumner County Medical Society, bank president, aged 69, died, March 3, of cerebral hemorrhage

Frank Elliot Bateman & Somerville, Mass. Harvard University Medical School, Boston, 1894, veteran of the Spanish American War for many years city physician on the courtesy staff of the Somerville Hospital, aged 70, died, April 5, of heart disease

Joseph Cyrus Bradfield & Lima, Ohio, Ohio State University College of Medicine, Columbus, 1911, served during the World War, aged 47, on the staffs of the Lima Memorial Hospital and St. Rita's Hospital, where he died April 14, of pneumonia

James A. Moore & Marshall, Texas, Vanderbilt University School of Medicine, Nashville, Tenn. 1899, past president of the Harrison County Medical Society, chief surgeon of the Texas and Pacific Railway Employees Hospital, aged 62, died, March 12

Zert Huff Fodrea, Westfield, Ind., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1888, member of the Indiana State Medical Association, past president of the Hamilton County Medical Society, aged 79, died, April 21

Runyan Lee Butler & Clovis, N. M. University of Arkansas School of Medicine, Little Rock, 1928, secretary and past president of the Curry County Medical Society, aged 31, died April 1, in a hospital at Little Rock, Ark. of pneumonia.

Thomas Craig Detwiler, Lancaster, Pa. University of Pennsylvania Department of Medicine, Philadelphia 1881, formerly on the staff of the Lancaster General Hospital, aged 76, died April 15, in St. Joseph Hospital, of diabetes mellitus

Ernest A. de Bordenave, Franklin, Va. Medical College of Virginia, Richmond, 1899, member of the Medical Society of Virginia for many years postmaster, aged 61, died, April 6, in the Radford Hospital of cerebral hemorrhage

Ernest Linwood Hayford, Chicago, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1890, aged 71, died April 16, in the Washington Boulevard Hospital of carcinoma of the thyroid

William Henry Bahl, Chicago, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1904, aged 63, died, April 23, in the Illinois Masonic Home, Sullivan of mitral insufficiency

Mabel Harvey Falk Bancroft, Philadelphia, Woman's Medical College of Pennsylvania, Philadelphia 1903, served in France during the World War, aged 54, died April 28, in the Woman's Hospital, of heart disease

William Harrison Mallory & Joplin, Mo. Medico-Chirurgical College of Kansas City 1905, aged 57, on the staffs of St. John's Hospital and the Freeman Hospital where he died March 15, of agranulocytosis

Robert L. Miller, Waynesboro, Ga. University of Georgia Medical Department, Augusta, 1891, member of the Medical Association of Georgia, aged 65, died, March 31, of hypertension and nephritis

Irvin Isadore Davis, New York, University of Oregon Medical School, Portland 1935, intern at the Mount Sinai Hospital, aged 23, died April 6, in Portland, Ore., of carcinoma of the pancreas

Sidney Adair Brevard & Deeson, Miss., College of Physicians and Surgeons, Memphis, Tenn., 1907, served during the World War, aged 50, died April 19, in the Baptist Hospital, Jackson, of uremia

Alexander Rae Evans, Ardmore, Pa., Medico-Chirurgical College of Philadelphia, 1905, for many years a member of the Lower Merion Board of Health, aged 69, died, April 20, of cerebral thrombosis

Mary Taylor Bissell, Brooklyn, Woman's Medical College of the New York Infirmary for Women and Children, New York 1881, aged 82, died, April 1, of uremia, chronic nephritis and Paget's disease.

William H. Peters, Cincinnati, Miami Medical College, Cincinnati 1909, for many years city health officer, aged 54, died March 13, in the Good Samaritan Hospital, of coronary arteriosclerosis.

Lundy Nathan Barnard, Muskogee, Okla., Memphis (Tenn.) Hospital Medical College, 1911, on the staff of the Veterans Administration Facility, aged 58, died, April 29, of angina pectoris

Alexander David Berow, Brooklyn, University of the City of New York Medical Department, 1893, aged 66, died, April 22, in the Israel Zion Hospital, of injuries received in an automobile accident

James L. Henderson, Osceola Mills, Pa., Medical College of Ohio Cincinnati, 1882, member of the Medical Society of the State of Pennsylvania, aged 83, died April 20, of cerebral hemorrhage

Helen Simonds Childs, Simsbury Conn., Boston University School of Medicine, 1890, aged 84, died, April 8, of toxemia following acute obstruction of the common bile duct due to stone.

Adelbert Ghadden Bush, Grand Rapids, Mich., University of Buffalo School of Medicine, 1881, Civil War veteran, aged 87, died April 12, of cerebral arteriosclerosis and chronic myocarditis

Frances S. Konrad Filipiak, Cleveland, Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1898, aged 60, died, April 22, in the Woman's Hospital

John W. Bradfield, Austin Texas, University of Texas School of Medicine, Galveston 1903, medical superintendent of the Austin State School, aged 58, died, April 23, of coronary occlusion

J. Edwin Allen, St. Louis Missouri Medical College, St. Louis, 1896, aged 69, died April 23, in the Bethesda General Hospital, of carcinoma of the prostate with metastasis to the liver

Beatrice Victoria Burg, Oakland, Calif., University of Texas School of Medicine Galveston 1922, member of the California Medical Association, aged 43, died April 4, of heart disease

Everett Joshua Peek, White Hall, Ill., Chicago College of Medicine and Surgery, 1907, aged 57, died, March 21, in Houston, Texas, of coronary occlusion and chronic hypertension

Charles Curtis Page, Richmond, Va., University of Virginia Department of Medicine, Charlottesville, 1886, aged 72, died March 8, of uremia, chronic nephritis and hypertension

James Braxton McKee, Glade Springs, Va., Vanderbilt University School of Medicine, Nashville, Tenn., 1891, member of the Medical Society of Virginia, aged 76, died, March 17

Daniel Edward Cripe, Hillisburg Ind., American Medical College Indianapolis, 1895, aged 85, died, April 8, in the Clinton County Hospital, Frankfort, of cerebral hemorrhage

Nasib Daud Barbari, Niagara Falls N. Y., American University of Beirut School of Medicine, 1892, aged 62, died suddenly, April 16, in the Memorial Hospital, of myocarditis

E. Stella Perrigo, Pipestone, Minn., Hahnemann Medical College and Hospital, Chicago, 1886, aged 83, died, March 25, at Mound, of hemorrhage due to carcinoma of the uterus

John Andrew Doerner, Cumberland, Md., University of Maryland School of Medicine, Baltimore, 1877, aged 79, died, April 7, of bronchopneumonia and cardiac dilatation

E. H. Wyman, Estill S. C., University of Georgia Medical Department, Augusta, 1889, aged 66, died, March 25, in the Columbia (S. C.) Hospital, of coronary thrombosis

John A. McHugh, Chicago, Harvey Medical College, Chicago, 1901, aged 62, died March 28, in the Garfield Park Community Hospital, of hypertensive heart disease

Ransom W. Edden, Janesville, Wis., Bennett College of Eclectic Medicine and Surgery, Chicago, 1891, aged 67, died April 15, of cerebral hemorrhage and hemiplegia

David Robert Bussdicker & Dayton, Ohio, Miami Medical College, Cincinnati, 1908, aged 64, died, April 17, in the Miami Valley Hospital, of cardiorenal vascular disease

Oliver Sloan Haines, Philadelphia, Hahnemann Medical College of Philadelphia 1882, professor emeritus of materia medica at his alma mater, aged 75, died, May 1

Gordon Van Buren Fletcher, Chicago, Meharry Medical College Nashville, 1930, aged 38, on the staff of the Provident Hospital, where he died April 11, of nephritis

George N. Cox, Mount Sterling Ky., University of Louisville School of Medicine 1885, aged 74, died, April 15, in the Mary Chiles Hospital, of intestinal obstruction

Charles Stockton Stafford, Tampa, Fla., Hahnemann Medical College and Hospital of Philadelphia, 1889, aged 70, died, March 24, of carcinoma of the bladder

Donald Herman Hesse Till, Charleston, S. C., Medical College of the State of South Carolina Charleston 1931, aged 32, died, March 22, in Williamsport, Pa.

H. H. Bainter, Coshocton, Ohio, Baltimore Medical College, 1893, aged 78, died, April 23, in the City Hospital, of pneumonia, following fracture of his hip

William H. Doak, Martinsville, Ill., University of Wooster Medical Department, Cleveland, 1874, aged 93, died, April 23, of arteriosclerosis and chronic nephritis

Edward Payson Cooper, Maplewood, N. J., University of the City of New York Medical Department, 1871, aged 88, died, April 10, of cerebral hemorrhage

Gordon Stanton, Hastings, Fla., George Washington University School of Medicine, Washington, D. C., 1905, aged 66, died, March 31, of chronic myocarditis

Emma E. Olson Cummings, Milwaukee, Hahnemann Medical College and Hospital, Chicago 1899, aged 66, was found dead, April 11, of chronic myocarditis

BLOOD IN ARTHRITIS

To the Editor—In the interesting report on the "Blood in Arthritis" by Dr Hartung and his co workers (*THE JOURNAL*, April 25, p 1448) there seems to be an inconsistency which I should like to have explained. On page 1449 the authors state that "the elevated nonfilament count in slightly over half of the patients with osteo-arthritis is worthy of comment. These abnormal conditions in osteo-arthritis may be due to associated rheumatoid disease or focal infection." In the summary of their paper on page 1452 the writers assert that "the finding of a normal nonfilament percentage in many cases of osteo arthritis certainly suggests that infection plays no role in this condition." Clearly the writers are impaled on the horns of a dilemma. They must either admit that the presence of an elevated nonfilament count is not an indication of infection, which is contrary to their opinion as stated in *THE JOURNAL*, March 4, 1933, or they must admit that in at least half of their cases of osteo arthritis some infectious factor plays an active role. If evidence such as Dr Hartung and his co workers have cited points to a possible infectious factor in a fairly high percentage of cases of osteo arthritis, it seems wise to follow that lead. It appears particularly important to me when it is correlated with the clinical fact that in a group of osteo arthritis cases analyzed recently, approximately 40 per cent of the patients had demonstrable foci of infection. It would be interesting to know whether Dr Hartung has made any correlation between the blood picture and the presence of focal infection in the cases of osteo arthritis which he has studied.

There seems to be a general reluctance, today, to admit that infection may play a part in the etiology of any case of osteo arthritis. Indeed, there are some who state dogmatically that rheumatoid arthritis is an infectious disease and that osteo arthritis is a degenerative process and therefore noninfectious. These authors seem to forget that many degenerative pathologic conditions are infectious in origin. While it may be justifiable to attempt to make a differential diagnosis between rheumatoid arthritis and osteo-arthritis, clinically, surely we are not as yet prepared in the present stage of our knowledge to make any sharp etiologic distinctions between these two types.

BENJAMIN H. ARCHER, M.D., New York

NOTE.—This letter was referred to Dr Hartung who sends the following reply:

To the Editor—It has been pointed out by investigators that a rise in the immature leukocytes is the result of stimulation of the blood-forming organs by the absorbed products of infection. We found the nonfilament count elevated in 96 per cent of our patients with rheumatoid arthritis, in many of whom no focus of infection was demonstrable other than active joint involvement. In our group of patients with osteo arthritis presenting clinical symptoms in every case, 47 per cent showed a normal blood count. In those osteo arthritic patients with an elevated nonfilament count a number were found to have mixed arthritis, while the rest of the group presented a variety of focal infections. Focal sepsis alone gives an elevated nonfilament count (Pepper, O. H. P., and Farley, D. L. *Practical Hematological Diagnosis*, Philadelphia, W. B. Saunders Company, 1934). Our results suggest then, that in osteo arthritis an increased nonfilament count is indicative of an added factor to the intrinsic arthritic process. The doctor's figures on the incidence of focal infection in osteo-arthritis approximate our own observations. It must be remembered that a similar frequency of focal infection has been reported in routine examinations of presumably healthy adults (Sydenstricker, Edgar and Britten R. H. *Am J Hyg* 11:73 [Jan] 1930). To avoid

the fallacy of nonsequitur it must be realized, therefore, that the mere presence of an infectious focus does not necessarily endow it with an etiologic relationship to the long standing osteo arthritis it accompanies.

Our correspondent's concern for the classification of osteo arthritis as an essentially degenerative disease is not supported by the trend of published work and thought on the subject. Further evidence must be awaited than now exists before the complicating factor of focal infection in a part of the disease group can be accepted as the etiologic agent in the disease as a whole.

EDWARD F. HARTUNG, M.D.

OTTO STEINBUCKER, M.D.

New York

COMMITTEE ON CONTRACEPTIVE PRACTICES

To the Editor—The report of the American Medical Association's Committee on Contraceptive Practices contains a quotation from a book written by Mr Leon F. Whitney and myself. This quotation gives the impression that we do not believe in birth control. This is directly contrary to the facts. We certainly believe that birth control has brought with it great dangers. As every one recognizes it has reduced the birth rate among the more intelligent portions of the community to a dangerous degree. The remedy, however, does not lie in a futile attempt to prevent the restriction of births. Contraception is here in full force and is bound to stay.

The case is exactly like that of the mechanization of industry. It has, indeed, brought great dangers but it is useless to talk of getting rid of it. If the birth rate of a century or more ago prevailed together with the modern death rate, the children who are now in school would see in this country a population much greater than that of China. That would mean almost immeasurable poverty, misery, disease and war.

Because of this both Mr Whitney and myself believe that more birth control rather than less is the remedy for the present undesirable situation. What is needed is more birth control among the less intelligent, less efficient and more self-indulgent parts of our population; this presumably will go far toward raising the birth rate among the more intelligent, efficient and self-controlled portions. There is a small but growing body of evidence that in groups in which birth control is almost universal the differential in the birth rate is in the right direction. That is the homes where children are well trained and presumably receive a good biologic inheritance contain larger families than do homes of the opposite type. This is true not only of limited groups such as college graduates but of whole cities such as Stockholm. The cure for the evils of partial birth control such as we now have in America, appears to be complete birth control among all classes.

There are other points in which the report of the American Medical Association's committee shows lack of care. For example there is a direct contradiction which suggests an unsatisfactory compromise between two opposed factions. We read for example, that when a physician for "other than medical reasons considers it improper to aid his patient to practice contraception" he "should not be criticized," although he lets these other reasons guide his actions. This, be it noted, is said to be the case even when from a medical standpoint pregnancy is contraindicated. A later sentence says "When a medical reason for avoiding pregnancy exists it is the duty of the attending physician, regardless of his personal beliefs [italics mine] to inform the patient of her physical condition and the hazard of pregnancy." Such an attempt to sit on both sides of the fence is not worthy of the medical profession. I do not believe that either this attitude or the unduly conservative way in which the vital task of perfecting the

methods of contraception has been tabled by the American Medical Association represents the real opinion of American physicians

The chief trouble with the report is that it treats contraception as if it were a purely medical matter. This is no more true than that sanitation is purely an engineering problem. The technical skill, to be sure, must be furnished in the one case by physicians and in the other by engineers. But both contraception and sanitation are great social problems and concern the whole people. The social aim of birth control is that plenty of births should take place in the right kind of families and few in those in which the children are likely to be poorly trained as well as poorly endowed by nature. The American Medical Association has ignored this aspect of birth control and has rejected the great task of teaching proper contraceptive methods to every level of society. By failing to recognize this the American Medical Association has done a great injustice to itself, to its members and to the public.

ELLSWORTH HUNTINGTON, New Haven, Conn.
President, American Eugenics Society

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CURE OF MALARIA

To the Editor—How can one tell whether a relapsed tertian malaria case originally developed in another country is cured when the parasites do not show in the blood any more? Is quinine contraindicated in presence of blood in the urine? Please omit name. M D New York

ANSWER—If repeated examinations of the blood by means of the thick film method are negative for the parasites, the chances are altogether in favor of the infection having been cured. The cultivation of the malaria plasmodia after the method of Bass and Johns may be used to determine the question of cure. This method has been in use in the Calcutta School of Tropical Medicine for some years, with the result that in some cases of malaria in which the blood is repeatedly negative on examination microscopically a positive result is obtained by the culture method.

With regard to the use of quinine in the presence of blood in the urine, the drug should be used with great caution. If the case is one of hemoglobinuric fever there is still some question as to whether quinine should be administered, but it is believed that the trend of opinion is in favor of the administration of the drug, owing to the serious character of the condition. However, it would probably be safer to use plasmochin or atabrine in such cases.

PASSIVE TRANSFER METHOD IN ALLERGY

To the Editor—In an article on allergy in a recent issue of the *Cleveland Clinic Quarterly* a writer referred to a passive transfer method of testing for allergy. Can you give me further information as to the indications, technique and results of this method? Please omit name.

M D New York

ANSWER—The phenomenon of passively sensitizing a normal skin with the serum of an allergic patient was described in 1921 by Prausnitz and Küstner. Elaborating on this work, Coca and Grove demonstrated that the sensitizing properties are present in the blood serum when the allergic individual exhibits a positive skin reaction to an antigen, that many antibodies or reagins, as they are frequently termed, may exist in the same serum, and that each reagin will react specifically only with its related antigen. The serum is obtained from the sensitive individual under sterile precautions. In the absence of a positive Wassermann reaction it may be used to sensitize the skin of a normal individual. It may be used undiluted or diluted with sterile physiologic solution of sodium chloride to 1:10 or more, depending on its reagin content. One-tenth cc is injected intracutaneously in a number of sites at least 2 inches apart, the forearm back or thigh of the normal indi-

vidual being used. These sites are marked with indelible ink or mercuriochrome. After twenty-four hours each of these places may be tested with a suspected antigen by either the scratch or the intradermal method. A modification of this method of testing the sensitized site was described by M. Walzer, who found that on the ingestion of a food to which the patient is sensitized, preferably on an empty stomach, a reaction will occur in the passively sensitized site after about twenty minutes. With this method of ingestion, however, all sensitized sites will react if the antigen is a cause of the allergy. The sites may be retested after twenty-four hours, a different antigen being used for each place.

It may be noted that this method of testing by passive transfer is much more complicated and requires greater experience than the method of testing the patient directly. Its clinical usefulness is limited to patients with extensive eczema in whom the skin is unfavorable for tests, to patients with marked dermatographism, and possibly to infants on whom tests cannot be made without too great a struggle. It does not replace but is merely supplementary to the ordinary methods of allergic examination.

STAMMERING

To the Editor—In the Dec. 14, 1935 issue of *THE JOURNAL* 10 Queries and Minor Notes there was a question on stammering. In the reply it was stated that Cleveland shows the best school statistics as it has practically eliminated adult stammering. Will you kindly let me know where these statistics have been obtained and where I can write to learn the method of treatment used by the Cleveland schools?

I W KARLIN M D Brooklyn

ANSWER—Statistics of speech correction in the Cleveland schools may be obtained by writing to the speech supervisor of the Cleveland schools. Statistics have been kept since the method was installed in 1918. These statistics were published in a 1930 report of the meeting of the American Society for the Study of Disorders of Speech, under the chairmanship of Dr. Elmer L. Kenyon of Chicago. In the same report are statistics of the Omaha schools which use the same method, but Cleveland has had the method over a longer period of years.

SENSITIVITIES IN RUBBER MANUFACTURING EMPLOYEES

To the Editor—Trouble we do not know just from what is occurring in the manufacture of rubber goods. We make rubber shoes the same as any other rubber manufacturer. Employees get a rash. What I am trying to do is find out if possible whether other companies are having similar trouble, the etiology and the treatment. We buy the raw rubber and go through the process until it is a complete shoe but where we have our trouble is in the making of rubbers, galoshes and rubber boots.

M D Illinois

ANSWER—Most companies that manufacture rubber goods experience some difficulty on account of skin diseases. In some instances the skin diseases are encountered along with systemic diseases such as from benzene (or its homologues) or from carbon tetrachloride or trichloroethylene. More often the dermatitis is the sole evidence of a harmful action of the chemicals utilized. At present the chief offending agents are the rubber accelerators, although on occasion rubber itself has been held responsible. Among other accelerators or antioxidants now or lately in use, the following have been found to be skin irritants: diortho-tolylguanidine, diphenyltolylguanidine, paraphenylenediamine, hexamethylenetetramine (methenamine), thiocarbonyl, ethyldecaniline, formaldehyde-aniline, methylenediamine, anhydroformaldehyde-aniline and anhydroformaldehyde-paratoluidine (Hamilton). Other substances that should be the recipient of concern are dichloroethylene, antimony sulfides, sulfur chloride, carbon bisulfide, naphtha, soapstone, boot varnishes and divers diamines. So rapidly are developments made in the rubber industry with respect to accelerators that always the rubber chemist is ahead of the toxicologist. It is believable that agents newer than those listed may be in some use.

It is suggested that patch tests be carried out on various workers, using as test materials rubber without any accelerator, rubber containing the individual accelerators, rubber before and after vulcanizing, and so on. The cause is likely to be found without difficulty in the accelerators—one or more. If the patch tests with such materials are consistently negative, tests should be extended to various solvents, varnishes, coloring agents and fillers. The cause having been found, the treatment is simple—eliminate the irritant. Nonirritating or less irritating accelerators usually are available. So soon as the causative agent is removed, the usual accelerator dermatitis speedily clears up with or without treatment.

The patch test mentioned may be carried out in various ways. The simplest is to apply small squares of the test material directly to the extensor surface of the forearm or

thigh, cover over gauze and a layer of dental drumming or cellophane held in place by adhesive plaster. The contact should remain not less than twenty-four hours in the absence of troublesome irritation. Seventy-two or ninety-six hours sometimes is preferable for substances of low irritating properties.

NO MUCUS FORMING FOODS

To the Editor—I am so frequently asked by patients about foods that cause mucus that I am referring the question to you as I can find no scientific authority that answers the question. Self-styled food experts tell them that milk, cheese and eggs all form mucus and should be eaten very sparingly and never if they have a cold or any other condition accompanied by mucus such as sinus disease or mucous colitis. My teaching has always been that there is no such proof of this contention except possibly in cases of food allergy in which any food eaten that the patient is sensitive to might cause a mucous colitis.

M D California

ANSWER—There seems to be no scientific authority for the assertion that any food forms mucus. Normally there is a thin coating of mucus over the gastric mucous membrane and careful studies of the various foods in the normal human stomach fail to reveal any increased mucus production on the part of the mucous membrane with practically all varieties of food. In most instances increased mucus is due to a condition of the mucosa rather than to the type of food that is introduced. Increased production of mucus therefore suggests irritability or inflammation of the mucous membrane whether it would be due to gastritis, enteritis or colitis. When such is the case the entrance of any irritating food may be followed by an increased production of mucus. There is absolutely no evidence that this effect is due to milk, cheese or eggs. On the contrary they usually form part of the bland diet which is most acceptable to these patients. Intragastric studies on milk, cheese and eggs in healthy subjects fail to show any increased production of mucus. In fact failure to handle these foods properly may result in increased intestinal putrefaction with the appearance of mucus in the bowel. This has been pointed out particularly regarding the influence of egg white in certain forms of intestinal putrefaction. Chronic inflammatory conditions of the mucosa frequently follow infections of the upper respiratory tract and are usually accompanied by an increase of mucus regardless of the type of food ingested. Furthermore, it is now generally known that much of this postural material as well as bronchial secretion may actually be swallowed and may accumulate in the stomach.

The correspondent is entirely right in assuming that there is no scientific proof of this contention and it is generally acknowledged that when food allergy exists the specific food in question may cause an allergic response in the mucosa in any part of the digestive tract.

DENICOTINIZED CIGARS AND CIGARETS

To the Editor—I meet patients who have been advised by physicians or friends to smoke so-called denicotinized cigarettes or cigars. They get some comfort from the belief that the nicotine has been removed but do they actually receive any benefit? Is the nicotine extracted? Are not carbon monoxide and the essential oils of tobacco even more harmful than nicotine? Does it make any difference whether the smoke is inhaled or not? Please omit name.

M D Massachusetts

ANSWER—Benefit from the use of so-called denicotinized cigarettes or cigars, instead of the ordinary brands depends on the relative amount of tobacco so consumed. The various brands of so-called denicotinized tobaccos so far examined have been found to contain from 0.5 to 1 per cent of nicotine by weight, as compared with an average of 0.8 per cent for West Indian cigarettes, 1.5 per cent for Oriental brands, 2 per cent for the common blends, which constitute the bulk of popular consumption, and 2.5 per cent for the straight domestic brands. It appears that the special processing to which such tobaccos have been subjected removes a considerable part of the nicotine originally present but that they are generally composed of high nicotine containing tobaccos to begin with, so that the residual nicotine present may still be much higher than that of certain brands of cigarettes not so treated.

The amount of nicotine actually absorbed depends not only on the nicotine content of the tobacco used but also on the amount of such tobacco consumed and the manner in which it is smoked. If the smoker relies on the advertised claims and increases either the number of cigarettes smoked, the length of cigarette consumed or the size of cigarette or cigar used, he may suffer from an actual increase in the amount of nicotine absorbed. Inhaling the smoke also appreciably increases the amount of absorption of smoke constituents. If the higher cost

of the specially treated cigarettes induces the smoker to economize in their use, he may indirectly benefit from the lessening in the actual amount of tobacco used.

Nicotine itself is held responsible for the production of extrasystoles and other cardiac arrhythmias, the development of "tobacco amblyopia" and the aggravation of thromboangiitis obliterans or other circulatory disturbances. Other constituents of the tobacco smoke must be responsible for the local irritation of the mucous membranes of the nasopharynx, the conjunctiva and the larynx, leukoplakias of the buccal mucosa and cancers of the lower lip as well as for the allergic manifestations that have been described. The carbon monoxide content of cigarette smoke is usually too low to produce clinical symptoms although occasionally it may play a part in the production of headaches.

IMPORTANCE OF HAND AND FOOT ANOMALIES

To the Editor—A friend has one extra toe being the great toe on each foot the first four toes including the extra one are webbed but other wise he is apparently normal. One brother, one sister and his mother have the same characteristic plus a peculiar articulation of the thumbs in which the joint between the proximal and the middle phalanx points convexly toward the index finger when the thumb is abducted. He has another brother with five toes with a webbing of the third and fourth toes on both feet and the webbing of the middle and ring fingers of the right hand. He also has one brother and two sisters normal so far as these characteristics are concerned. His father is also normal in this respect. Neither he nor any of his brothers or sisters is married so that there have been no children in the third generation. He does not know concerning his mother's parents and her brothers and sisters living as to these characteristics but he thinks they are normal. 1 What is the name given to this peculiarity? 2 If he marries a normal woman, what will be the likelihood of this characteristic appearing in his children and in his grandchildren? 3 If there is likelihood of this appearing in his children, what proportion of each sex will be likely to show this characteristic? 4 If his sisters and brothers each marry to a normal mate what would be the answer to questions 2 and 3 in each case. Please omit name.

M D Missouri

ANSWER—1 From the description it appears that the condition is one involving a doubling or twinning of the big toe associated with webbing of the other toes.

2 All, or nearly all, hand and foot anomalies are inherited as mendelian dominants. Since no intermarriage of close relatives has taken place, all individuals showing the anomalies are heterozygous (having both a dominant and a recessive gene). A heterozygous individual mating with a pure recessive (in this case a normal person) would be expected to produce affected and normal children in equal numbers.

3 Since these hand and foot characters are not sex linked, the two sexes would be equally affected.

4 The normal brothers or sisters of an affected person do not carry the gene for the anomaly and therefore would not pass it on to their children.

HAIR DYES

To the Editor—Is there any perfectly harmless method of gradually restoring a brown color to prematurely gray hair in a young man—a method that can be used at home? Please omit name.

M D, Nebraska

ANSWER—No, there is no perfectly harmless hair dye. The least harmful according to Alfred Perutz (*Handbuch der Haut u. Geschlechtskr.* 1934) are those made of combinations of henna, the powdered leaves of Lawsonia inermis, and rengé, the powdered leaves of the indigo plant, indigofera argentea. Varying amounts in the mixtures of the two dyes give colors varying from blond to black.

More dangerous is silver, which, carelessly used, has been known to produce generalized argyria. Dyes containing lead have been popular in the past and are still advertised as "gradually restoring the natural color." Lead does act gradually, combining with the sulfur in the hair, but there is danger of resulting plumbism. Silver and lead dyes are the only ones that will give anything like a satisfactory color when used at home. Of course there is much more danger of poisoning from them under these circumstances than if used by an expert. If the patient insists on dyeing his hair, let him go to the best hairdresser available to get an expert job, braving the danger of resultant dermatitis, which is, after all, not a frequent occurrence, or hair dyes would not long survive. The other alternative much the wiser, is to accept gracefully the distinction nature is bestowing on one.

SYPHILITIC AORTITIS

To the Editor—A man, aged 42 5 feet 8 inches (173 cm) tall 170 pounds (77 Kg) in weight has had anginous pains (with mostly minor attacks) and with a distribution to both jaws radiating to the back and also subinternally, increasing in frequency in the last six months. A recent Wassermann and Kahn test has shown a 4 plus reaction. On percussion the ascending aorta seems to be much dilated. My prognosis is syphilitic aortitis. A recent electrocardiogram does not reveal any myocardial involvement. The heart sounds seem to be normal and the heart does not appear to be enlarged. The blood pressure is 114 systolic 75 70 diastolic. Considering that this is a vascular type of syphilis am I justified in withholding arsenicals? I am giving the patient a saturated potassium iodide solution in ascending doses also 2 cc. of a 2.5 per cent bismuth subtartrate solution intramuscularly twice weekly. Is a soluble bismuth preparation reliable? When in your opinion should treatment with arsenicals start? What is the prognosis of such cases? Would you advise more radical treatment than mentioned? Kindly omit name

M D, New Jersey

ANSWER—The clinical diagnosis of syphilitic aortitis with possibly a beginning aneurysm is justified in this case. Cardiovascular syphilis in general should be treated more cautiously and less intensively than other forms of syphilis. There are at present two schools of thought relative to the treatment of cardiovascular syphilis, the one favoring the milder and slower acting remedies such as mercury, bismuth and the iodides, the other advocating more energetic treatment with arsenicals plus mercury and iodides. Bismuth, on account of its low toxicity, is a particularly desirable drug to use and can often be employed with excellent results to the exclusion of the arsenicals. A soluble bismuth preparation has no advantages over an insoluble one, such as the salicylate. In view of the different opinions expressed by various authorities, a conservative opinion would favor intermittent treatment with bismuth compounds and iodides over a long period of time before resorting to the arsenicals. The latter if used at all should be given cautiously and in small doses. The prognosis in cardiovascular syphilis must be guarded, as the outlook in general is grave. The value of rest, the avoidance of physical and nervous strain, and general measures should be emphasized in the management of these cases.

WASSERMANN FAST SYPHILIS

To the Editor—I have under my care a married woman aged 23 who was recently delivered of a male infant. On routine study fourteen months ago it was discovered that her blood was positive for syphilis. She was then started on intensive antisiphilitic treatment which has consisted in the main of alternating courses of a bismuth compound and neoarsphenamine each course consisting of ten weekly injections. The dose of the neoarsphenamine was from 0.45 to 0.6 Gm. that of the bismuth compound 1 cc. Serologic tests done from time to time have remained consistently positive. The last reading was as follows: Wassermann, 4 plus Kolmer strongly positive modified Hinton, positive, Kahn 3 plus. While the period of treatment is slightly more than a year should not one expect some changes in these tests? Incidentally the patient is a responsible person and denies any knowledge of the infection. Is it not quite likely that I may be dealing with syphilis of congenital origin which I have been taught, is much more refractory to treatment than the acquired form. Would a spinal fluid Wassermann test be indicated at this time?

M D Massachusetts

ANSWER—The serologic response of syphilis even when intensively treated with adequate courses of bismuth preparations and neoarsphenamine shows considerable variation. Before the case is classified as Wassermann fast at least another year of treatment should be administered. Unless there should be found some characteristic sign the disorder should be considered as acquired rather than congenital. A spinal fluid Wassermann test should be made at this time to rule out the presence of asymptomatic neurosyphilis.

UMBILICAL HERNIA

To the Editor—What would you suggest for an umbilicus that protrudes about half an inch in an infant 2 months old?

SAMUEL C. KARLAN M D Danmora N Y

ANSWER—A protrusion of the umbilicus may result from (1) the persistence of remnants of the vitello-intestinal duct and urachus or (2) the presence of a sac of peritoneum in the umbilical ring where the fetal vessels have passed, that is, a hernia. The question as stated does not give sufficient information for identification. It is therefore difficult to tell which treatment to recommend.

In general it may be said that, if the protrusion is solid and the result of persistence of the rudimentary structures, treatment consists in excision. The umbilicus with its protrusion or tumor, as the case may be, is excised by an elliptic incision. This should be done carefully, as there may be a communication with a rudimentary Meckel's diverticulum.

An umbilical hernia, on the other hand, in a child so young frequently gets well without operation. The essence of treatment is to bring the recti together. Broad strips of adhesive tape are applied from one side of the abdomen to the other in such a way that the lateral tension is reduced. A felt pad may be placed over but not into the hernia. The strapping may be renewed as often as necessary, approximately once every week or two. This treatment hardly ever fails up to the age of 3. In a child over that age, operative treatment is usually necessary.

MENOPAUSAL DISTURBANCES

To the Editor—For the last nineteen years, following a panhysterectomy, a friend has had symptoms of persistent menopause. These symptoms consist of nervousness, hot flashes and headaches. At present she is 42 years of age. She has taken ovarian extract without relief. Is there any other preparation that could be of aid? Please omit name and town.

M D Kentucky

ANSWER—The prolonged period of distressing menopausal symptoms may be attributed to the fact that the patient had the panhysterectomy at the early age of 23. However, there must undoubtedly be a strong psychic factor in this patient. Many women can be relieved of their menopausal disturbances by the repeated hypodermic administration of estrogenic substance. The two preparations most commonly used in this country are amniotin (E. R. Squibb & Sons) and Theelin (Parke, Davis & Co.). It is well to give about 500 rat units hypodermically every second day. In addition, the patient should take either one amniotin capsule or one theelin capsule by mouth every day. If this dosage does not give relief, more frequent injections or larger amounts will have to be given. As soon as the patient feels distinctly better, the dosage may gradually be diminished. This treatment will have to be carried out over a long period. It is advisable also to prescribe a mild sedative, such as the bromides, or small doses of one of the barbiturates.

MEASURING CARDIAC LOAD

To the Editor—Please tell me how to figure heart load and mean pressure. I know that systolic 120 diastolic 80 pulse pressure 40, mitral efficiency three times 40 = 120. Keeping within the range of the systolic is normal. I know that systolic 160 diastolic 100 pulse pressure 60 mitral efficiency three times 60 = 180 shows the myocardium under undue strain. Now how do I find the heart load which I believe normally is around 50 and how do I find mean pressure which is around 72?

HENRY V. BROESER M D Hoboken N J

ANSWER—From the way the question is stated it is difficult to understand what the author has in mind. The cardiac load cannot be calculated from such simple measurements as blood pressure. The most important factors that maintain blood pressure are the force and rate of the heart, the volume and viscosity of the blood, the elasticity of the blood vessels, and the peripheral resistance. It is obvious that with all the complex factors influencing the blood pressure one can hardly compute the heart load from blood pressure measurements. In general, physiologic processes are very complex and their measurement, such as cardiac load, does not reduce itself to simple mathematical formulas, as implied in the question.

DIPHTHERIA AND SCHICK TESTS

To the Editor—1 Is it advisable to do a Schick test on all infants before giving diphtheria toxoid? Does the same apply to older children? 2 If toxoid has been given and a negative Schick test obtained when should the Schick test be repeated? 3 In the event a case of diphtheria occurs in a family should other children in the family previously found Schick negative be given the preventive antitoxin? 4 If a child has been given toxoid and then is exposed to diphtheria before the end of from six to eight weeks and no Schick test has been done, should antitoxin be given? 5 In children who have never had toxoid but are found Schick negative when should the Schick test be repeated? Please omit name.

M D Tennessee

ANSWER—1 It is not necessary to do a Schick test on infants before giving diphtheria toxoid. It is advisable to do a Schick test on older children before immunization.

2 It is desirable to repeat the Schick test one year after immunization.

3 If a case of diphtheria occurs in a family, preventive antitoxin should not be given to children who previously showed a negative Schick test.

4 It is not advisable to give preventive antitoxin to a child exposed to diphtheria from six to eight weeks after administration of diphtheria toxoid. It is best to do a Schick test first.

5 It is not necessary to repeat the Schick test in children who are spontaneously negative.

NONSPECIFIC PROTEIN THERAPY

To the Editor—What foreign proteins besides milk and typhoid vaccine would you suggest for supplementary protein therapy in my practice? What would you suggest as supplemental measures in rheumatism and acute and chronic arthritis and would streptococcus bacteriophage be satisfactory in those conditions? I have read Cecil's recent article but he mentions only milk typhoid vaccine and diphtheria. Is the milk put up in vials by some of the pharmaceutical laboratories potent enough or is freshly boiled milk the best?

M D Appleton Wis

ANSWER—One of the simplest and cheapest of foreign proteins is sterile normal horse serum, given in doses of from 2 to 5 cc intramuscularly. In rheumatism and arthritis the foreign protein that has been used most extensively is some form of *Streptococcus haemolyticus* vaccine administered in small doses either intramuscularly or intravenously. There is some difference of opinion as to the value of *Streptococcus haemolyticus* vaccine in the treatment of rheumatic conditions but it still has many strong advocates. The value of streptococcus bacteriophage would probably be proportional to the amount of reaction set up in the patient by the injection. On the whole, streptococcus bacteriophages have been disappointing in the treatment of streptococcal infections. Freshly boiled skimmed milk is usually preferable to the refined products put up by pharmaceutical laboratories, as the former is more likely to excite a febrile reaction.

DIFFERENTIAL DIAGNOSIS OF CATARACT DUE TO DINITROPHENOL

To the Editor—How can one differentiate between senile cataract from one due to dinitrophenol poisoning in a person 55 years of age? Please do not publish name.

M D New York

ANSWER—A cataract due to dinitrophenol is always bilateral although the condition in one eye may be more advanced than in the other. It appears from six to twenty months after the ingestion of the drug. The onset is rather slow requiring from three to six months before vision is seriously interfered with but afterward the progress is very rapid. The opacity is rather uniform and lies in the anterior and posterior cortex leaving the nucleus fairly clear until the terminal stage. There is apt to be more swelling of the lens than in the senile form. Immediately underneath the anterior as well as the posterior capsule there is most frequently a narrow zone of clear cortex that is practically the last part of the lens to become opaque. In many respects a cataract due to dinitrophenol resembles closely a true diabetic cataract.

TREATMENT OF FILARIASIS

To the Editor—I have a patient suffering from filariasis. The filariae have been seen in the blood. The only symptoms she complains of are weakness and milky white urine due to chyle. The patient has had many kinds of treatment during the last three or four years but they do not seem to have improved the disease at all. Sometimes the urine is normal for a period of months but at other times it is just the same as before. Kindly send me information concerning the latest accepted treatment of such cases.

GEORGE R HOPKINS M D Curaçao Netherlands West Indies

ANSWER—At present, experimental work suggests that the best hope of improvement in cases of filariasis and especially chyluria is to be derived by high voltage roentgen therapy. The technic is described by Golden, Ross, and O'Connor. *F W The Roentgen Treatment of Filariasis, Tr Roy Soc Trop Med & Hyg* 27 385 (Jan 31) 1934.

URTICARIA AFTER SAUER VACCINE

To the Editor—One week after the administration of 2 cc of Sauer pertussis vaccine (first dose), a child experienced a severe urticaria. How should I proceed in this case with regard to further doses? How serious a hypersensitivity may I have grounds to fear? Please omit name.

M D New York

ANSWER—It seems quite unlikely that authorized pertussis bacillus vaccine, injected into a nonimmune child would precipitate urticaria a week later.

Both laboratories authorized to make this vaccine for immunization grow the Bordet bacillus on Bordet medium enriched with human blood. Vaccine, so prepared, containing no trace of animal protein, should not sensitize or elicit anaphylactic reactions.

If the correspondent is certain that the child has not had whooping cough, and if one of the two authorized commercial vaccines is used the bilateral injections should be continued at

weekly intervals until a total of 8 cc has been injected. If the child is more than 3 years of age, a total dosage of 10 cc may be given. Immunization ought to be complete within several months after the last injection.

EFFECTS OF LOW HYDROCHLORIC ACID

To the Editor—In men past 50 what is the incidence of low hydrochloric acid? In alcoholic addicts is the tendency toward high or low hydrochloric acid? Please use initial only.

M D Alabama

ANSWER—In men past 50 the incidence of low or absent hydrochloric acid is at least 33 per cent, according to most authors. Seidlin and also Menlengracht found achylia to be present in 40 per cent of healthy elderly persons. Lipschutz observed an achylia in 33 per cent of a group of healthy individuals between the ages of 50 and 75. On the other hand, Schütz obtained an absence of free hydrochloric acid in only 15 per cent of elderly individuals he examined.

In alcoholic addicts the tendency is toward low hydrochloric acid although high and normal values are frequent. In cases of long-standing alcoholism particularly the degree of acidity is likely to be low, whereas in the early cases hyperacidity is not rare.

PREPARATIONS USED INTRAVENOUSLY

To the Editor—I have an Epitome of the U S Pharmacopeia and National Formulary also a 1935 copy of New and Nonofficial Remedies, and have subscribed for the 1936 edition but these books do not solve my prescribing problems. Little is mentioned in the Epitome about intravenous or intramuscular or even subcutaneous medication yet drug houses are putting out ampules and such for this medication. Sodium chloride intravenously is used as normal salt solution so is sodium iodide sodium salicylate colchicine and various other drugs as examples of what I mean. Is it possible that you have a book which simply tells of the U S P drugs and N F drugs that are used intravenously intramuscularly or subcutaneously? If so please send me the names of the book or books so that I can solve the problem.

M D Ohio

ANSWER—Dutton's book on "Intravenous Therapy" (Philadelphia F A Davis Company, 1925) is the most extensive book on the subject at present available. The various other injection methods are discussed in Fantus's "Technic of Medication" (Chicago American Medical Association 1930).

BLINDNESS IN NEPHRITIC PATIENT

To the Editor—What are the tests for blindness in case of a delirious nephritic patient? This is a case in which an insurance company requires evidence of blindness to prove the attending physician's diagnosis. Please omit name.

M D Pennsylvania

ANSWER—In an instance of this sort in which subjective responses are out of the question objective tests have to be relied on. If the pupillomotor apparatus is in order, the contraction of the pupil by direct light stimulation is proof positive that the retina and the optic nerve at least as far as the corpora quadrigemina, are functioning. Direct and consensual contraction of each pupil will give positive information regarding the light perceiving function of each eye but does not permit of a measure of visual acuity. On the other hand, if the pupillomotor apparatus is not functioning, by reason either of disease or of drugs, there is no objective test that will allow of a diagnosis of absolute blindness.

SODIUM AMYTAL WITH THYMOPHYSIN

To the Editor—I have been trying to find out whether any one has had any experience in obstetrics with sodium amytal followed with thymophysin. It seems to be poisonous to the baby. I shall appreciate it if you will let me know if there is an incompatibility.

H C PAGEOTT M D Roanoke Va.

ANSWER—There are no special reports on the combined use of sodium amytal and thymophysin but there appears to be no reason why a baby should be subject to more danger following the use of these drugs than would result from a simple summation of their potential dangers. Sodium amytal does not often affect a baby in utero. Thymophysin, however, frequently causes disturbances in babies, as evidenced by the increased and irregular fetal heart rate and tumultuous temporary activity that frequently occur after the administration of thymophysin. This is claimed to be a preparation of thymus and posterior pituitary. The Council on Pharmacy and Chemistry declared thymophysin unacceptable for inclusion in New and Nonofficial Remedies (*THE JOURNAL* March 14, 1931, p 860) because "it is an unscientific preparation marketed under false claims as to its essential action as to its strength, and as to its safety for mother and child."

TREATMENT OF DIPHTHERIA CARRIERS

To the Editor—What can be done for a persistent diphtheria carrier?
Please omit name M D, Minnesota

ANSWER—Any abnormal local condition should be corrected. Particular attention should be paid to the tonsils, because frequently removal of enlarged or diseased tonsils in diphtheria carriers has resulted in the disappearance of diphtheria bacilli from the throat. At the same time the general health and personal hygiene of the patient should receive special attention.

DIPSOMANIA AND NYMPHOMANIA

To the Editor—What treatment do you advise for a woman aged 43 and physically well who is a dipsomaniac and also inclined to nymphomania? Would sterilization with irradiation be advisable? Please omit name M D, California.

ANSWER—Sterilization with irradiation or any form of physical treatment directed toward this patient would be a serious error. She apparently needs adequate psychiatric care, for both her symptoms are obviously in the realm of psychopathology.

THROMBOANGITIS OBLITERANS

To the Editor—Your answer to M D, Kansas, April 18, page 1413 is incomplete. It is evident from the letter that the patient does not suffer from rest pains. If he is suffering from intermittent claudication, surely this can be controlled with the use of tissue extract and 5 per cent hypertonic saline solution intravenously. If there is a painless ulceration, rest in bed, wet dressings and 5 per cent saline solution intravenously will also take care of it. If the ulceration is painful, peripheral nerve section will convert the ulcer into a painless one and the wound will usually heal without any untoward complications. In this instance also, saline solution intravenously, beginning with 150 cc. for the first dose and using 300 cc. for subsequent doses is a valuable adjunct. In the presence of gangrene of the toe, rest in bed, wet dressings and 5 per cent saline solution intravenously will check the spread and delimit the gangrenous areas. No ill effects have been shown following such prolonged use of saline solution. The contraindications to the intravenous administration of saline solution are myocarditis, nephritis and hypertension.

Typhoid vaccine injected intravenously has given good results in the opinion of many clinicians but the danger of administering typhoid vaccine intravenously is a thrombosis of the blood vessel. The contraindications to its use are myocarditis, nephritis, hypertension and arterio sclerosis.

Sympathetic ganglionectomy as you advised is not a simple procedure and subjects the patient to a major operation. It would be of no value if the occlusion in the blood vessel is organic in nature. Finally let me emphasize that the treatment of thrombo-angitis obliterans tends more to conservatism than to amputation.

THEODORE KAPLAN M D, New York

TREATMENT OF SYPHILIS

To the Editor—On page 1333 of the April 11 issue of THE JOURNAL Dr. George E. Knappenberger of Macomb, Ill. poses a question with reference to the fever treatment of a particular patient with neurosyphilis. The answer to this question advises against fever therapy in this individual patient. Whether or not this advice is sound could not be determined without much more information about the patient in question, including details as to his age, general physical status and amount and character of previous treatment. I take particular exception however to the last sentence of the answer which reads: "Fever treatment is indicated only in dementia paralytica."

Fever treatment is indicated in many types of neurosyphilis other than dementia paralytica among which may be specifically mentioned:

- (1) Preparetic asymptomatic neurosyphilis
- (2) Neurosyphilitic patients whose spinal fluid remains unimproved after large amounts of chemotherapeutic treatment
- (3) Primary optic atrophy
- (4) Selected patients with tabes particularly those with intractable lightning pains or gastric crises

In addition, fever therapy is also indicated in drug resistant syphilitic infection whether or not the nervous system is involved.

J. E. Moore M D, Baltimore

FREEMARTINS

To the Editor—Under Queries and Minor Notes in THE JOURNAL, April 11, page 1333 I saw an inquiry as to freemartins. Being interested in the breeding of high class cattle I was interested very much. I have found that twins when they have separate placentas always breed. This observation is substantiated in the work of Leon F. Whitney, who explains this phenomenon by stating that when a freemartin does not breed it is due to the fact that there was one placenta for both twins the blood of each flowing through the two and in the process it is assumed that the testicles of the male secrete a hormone which is carried by the blood to the female where it acts on her ovaries thus retarding their development. When twins are born from separate placentas the female is not likely to be sterile.

Council on Medical Education
and HospitalsAPTITUDE TESTS FOR MEDICAL
STUDENTS

CHARLES RUTHVEN FLACK
CHICAGO

'Then said they unto him, Say now Shibboleth', and he said, 'Sibboleth' then they laid hold on him, and slew him" Judges 12:6

Writers interested in the historical aspects of tests and testing are continually seeking the origins and antecedents of their subject, but no sooner does one discover that the Chinese made extensive use of tests and measurements before the year 1000 than another comes forward with an earlier example, and so on ad infinitum. Such historical delving is no doubt interesting and perhaps instructive but not extremely useful, and for most purposes a glance into the past, near or far, is most helpful when it brings to light the origins of movements or tendencies relating to specific testing problems, and most particularly when it traces the causes and developments that led to the production of specific tests.

In studying aptitude tests for prospective medical students, therefore, it might be well to look into the events leading up to their devising and early application, for the magnitude of the task of making up and administering these tests on such a wholesale basis was so great that it is very evident that they were undertaken to fulfil a definite purpose and were not merely academic exercises to enable students and scholars to display their ingenuity in psychologic gymnastics.

One finds two chief factors which were mainly responsible in turning the attention of the officers of medical schools toward the possibilities of aptitude tests in solving their problems. Perhaps the first factor, in time rather than importance, was the dissatisfaction of medical men in general and the faculties of medical schools in particular with the large number of failures among students admitted to the various schools.¹ This feeling of discontent was without doubt greatly intensified by the study of the scores of medical men on the Army Alpha tests reported by Yerkes² in 1921, but more or less public even in 1917 while the tests were being administered to the members of the draft army. Adverse public criticism was directed toward the state of affairs, and the faculties and officers of administration of the medical schools were thus brought to a vivid realization that the M D stamp was not necessarily a badge of great merit, intelligence and efficiency. Something had to be done or else the medical profession in general would suffer from the severe criticism because of the poor showing of many of the marginal individuals who had filtered into the ranks.

The methods of selecting applicants for admission to medical schools at that time were fairly rigidly prescribed in the by-laws of the Association of American Medical Colleges,³ but the requirements were quantitative rather than qualitative: sixty semester hours in an approved institution, and certain credits in premedical subjects, such as chemistry, biology and botany.

In addition to the dissatisfaction with regard to the finished product of the medical school there was a feeling, already mentioned, that the mortality in the medical courses (scholastic mortality, of course) was quite too high, for failures ran as great as 20 per cent in some institutions.

¹ Capen S. P. Premedical Education Bull. A. Am. M. Coll. 1:5 1926.

² Yerkes R. M. Memoirs of the National Academy of Sciences 1921 pp. 22-26.

³ Association of American Medical College By-Laws Minimum Entrance Requirements Bull. A. Am. M. Coll. 1:5 1926.

That this dissatisfaction was widespread is evidenced by the number of references and complaints found in the writings and utterances of the officials of the medical schools and members of the profession.⁴ No one, however, came forth with any constructive suggestions.

MULTIPLE APPLICATIONS

The second and more important factor that influenced the evolution of the medical aptitude tests was the ever growing number of applicants and applications for admission to medical schools. In the first two decades of the twentieth century the expansion of the medical schools seems to have kept pace with the increase in the number of students aspiring to become doctors, but by the fall of 1919 the schools began to note such increases in the number of students seeking admission that a large number of really eligible students had to be denied entrance each term even although many of them more than met the minimum requirements of the association. Then too, multiple applications began to be very common for the prospective student, fearing lest his application for admission to one school be refused, entered his request in another at the same time, or even a considerable number.

As might have been expected, the pressure for admission was greatest in the more thickly populated part of the country, in other words the so called effete East and accordingly it was here that one finds the first studies being made of the situation, although other sections soon followed suit. It is possible that the long experience with the selective processes on the part of the private schools and colleges in the East was largely responsible for the movement starting there. Cattell for example, had been making use of tests in a number of ways, and for various purposes including selection at Columbia since 1894.⁵

In 1926 Dr. Burton D. Myers was asked to make a report to the Association of American Medical Colleges on the problem of applicants and duplicate applications. This report⁶ delivered before the association at the thirty-sixth annual meeting, so impressed the members that Dr. Myers was authorized to continue his study and submit the results the following year. From that time on the report on applications became an annual event of greater or less importance at each conference of the association.

The first report by Myers noted that there were 20,093 applications submitted by 8,500 individuals seeking admission to medical schools in the fall of 1926 but that only 6,420 were accepted.⁷ Duplication of applications ran as high as twenty. During the discussion of the paper which followed the question was raised by Dr. A. S. Begg of the Boston University School of Medicine as to the methods used by the various schools in rejecting applications, and it was brought out very clearly that there was absolutely no uniformity of procedure in refusing admittance to students who fulfilled the minimum requirements of the association. Thus a man might be denied his permit to enter by ten institutions yet be granted one by the next.

In this manner the problem was brought more forcibly to the attention of all the members of the association and a number began to experiment with methods of selection beyond the minimum mentioned in the by-laws. Some, however, as previously suggested, had already begun to do something about it.

Thus Dr. John Wyckoff of the New York University College of Medicine reported at the thirty-seventh annual meeting

of the association on efforts to cope with the problem.⁸ According to his statements, beginning with the fall of 1919 New York University College of Medicine had received more applications from eligible students than could be admitted. By 1921 the excess was "so large that a definite plan for selection became necessary" (p. 1).

RECOGNITION OF NEED FOR SELECTIVE CRITERIA

A combination of scholarship and personality ratings was put into operation. Students with A and B averages in their collegiate work were admitted without further question provided of course, that their recommendations were satisfactory and that there was no definite reason for their being barred from entrance. Students with B— and C averages, however, were rated as to the desirability of their personalities, and the ones scoring highest on the scale used, which was a simple five point one, were admitted to fill any places not taken by the A and B men. After a year of trial it was felt that the personality ratings were too subjective and thereafter admissions were awarded entirely on a basis of scholarship in the premedical subjects. It was noted that the percentages of failures fell considerably almost at once.

The University of Nebraska was also experimenting with selective devices as was reported by Dr. Franklin D. Barker.⁹ The 'Nebraska plan' was to appoint advisers from the members of the liberal arts faculty to watch over the premedical students in order to note special medical aptitude and to encourage or discourage them as they saw fit. The report was rather vague as to methods of identifying aptitude and it seems that no general technique was followed. No special training was given to the advisers, and the dangers of proselytizing does not appear to have been considered. It is rather amusing to note that one of the results produced was an increase from 25 per cent to 70 per cent in the number of our own premedical students pursuing the medical course in our own college of medicine' (p. 18).

In the same issue of the *Bulletin* there appeared a report by Dr. Arthur C. Curtis¹⁰ of the University of Michigan Medical School on women students of medicine, in which he dealt with the qualifications of women medical students and their scholastic records. No comparison was made which indicated that they were better or worse than students of the opposite sex.

The presentation of these studies and their accompanying statistics aroused the association to still more activity, and the following year at the thirty-eighth annual meeting a report was made to the members by Dr. A. S. Begg,¹¹ chairman of the committee on medical education and pedagogics, in which he suggested, among other things, 'the creation of some sort of central agency' (p. 66) to handle the growing problem of applications for admission to the medical schools. However no action was taken, apparently, by the association at that meeting.

Dr. Myers¹² made another report covering the applications for admission to medical schools for 1927-1928 at the same meeting. It showed rather emphatically that the rush to break into the ranks of the medical men had not abated one whit, for there were now 23,590 applications from 11,282 individuals increases of 17 per cent and 32 per cent respectively, while the number of acceptances had increased only a trifle over 1 per cent to 6,495. It was noted that one individual, in a desperate

⁷ The actual enrolment in the fall of 1926 was 5,019.

effort to gain admittance, had applied to thirty-seven schools,¹³ while two others sent in applications to twenty-seven institutions in order to make sure of being accepted. The report ended with an appeal for a more careful method of selecting medical students but omitted this point (p. 198). "But do we know how to select superior men? Psychologists tell us that psychological tests furnish only contributory, not conclusive, evidence of ability. Recommendations are one criterion and does get. The personal interview, though very important, is again only a factor in the selection. The transcript of record shows only what the student has done under a certain environment and stimulus." One might almost believe that the man who wrote those words was a psychic and seer, so well do they indicate the development of the future.

Reports made at subsequent meetings of the association by Dr. Myers on the applications received by medical schools indicated a continued growth in the number both of applications and of applicants. No further mention of these reports will be necessary, for enough of them has been cited to show that the association was alive to the crying need for some selective criteria on which schools could base their admissions and rejections. All of the eighty-five schools comprising the association membership were well aware of the gravity of the situation.

At the thirty-ninth annual meeting of the association, held in Indianapolis Oct. 29-31, 1928, Dean Waldo Shumway of the College of Liberal Arts and Sciences of the University of Illinois delivered an address¹⁴ in which he suggested a liberal arts education as a premedical requirement—an education containing, of course, the prerequisites in science demanded by the medical schools. He did not, however, offer any study of the success of students possessed of such an education after they had entered the medical school, although many such were doing so, and no doubt records were available had he taken the trouble to look into them.

With the fourth volume of the bulletin the name was changed to the *Journal of the Association of American Medical Colleges*, but it continued to give a number of articles or reports dealing with the situation and its possible solution just as previously. Thus is found an interesting report by Dr. Begg¹⁵ reviewing conditions and making full use of much of the material and information in the Myers reports and also reports of the Council on Medical Education and Hospitals of the American Medical Association. Begg was chiefly interested in the scholastic mortality of medical students and presents tabulations showing this mortality in percentages as well as in absolute numbers, covering the period from 1907-1908 to 1925-1926. Percentages were fairly constant during that time, running around 18 to 20.

The associate dean of Columbia University College of Physicians and Surgeons also presented a study in this volume,¹⁶ a comparison of premedical and medical grades, in which he found that "the average grade of all the subjects studied at college was a rather better indication of the character of the work a student would do in the medical school than the average grade of the premedical required subjects alone" (p. 199). This was contrary to the experience of other investigators. The facts mentioned in the report, however, were not tabulated, nor were statistical measures given in a clear enough manner to make plain the exact comparisons implied in the title.¹⁷

Considerable interest was aroused over the phenomenon of multiple applications, particularly since the earlier report con-

cerning the student who had submitted thirty-seven applications and had been refused admission by the thirty-seven institutions.¹⁸ It was suspected in some schools and by not a few medical men that the number of applications might be an inverse indication of the student's ability. This suspicion was relieved, however, by reports at the fortieth annual meeting of the association, held in New York City on Nov. 7-9, 1929, presented by Adam M. Miller,¹⁹ dean of Long Island College of Medicine, A. S. Begg,²⁰ and Father Alphonse M. Schwitalla,²¹ dean of the St. Louis University School of Medicine. Although the number of cases covered by each investigator was somewhat too small to ensure a great deal of validity, nevertheless the evidence was pretty conclusive that the number of applications a prospective student submitted was no indication whatever of his ability to do satisfactory work in the medical school.

Feb. 18, 1929, Dr. David A. Robertson,²² assistant director of the American Council on Education, read a paper before the Annual Congress on Medical Education, Licensure and Hospitals at Chicago in which he ably reviewed the advance of scientific testing in various fields and then gave a detailed account of the beginnings of medical aptitude testing undertaken at George Washington University.

BEGINNINGS OF MEDICAL APTITUDE TESTING

He described the tests used as follows (p. 1404).

During the first ten minutes the student studies a diagram and a paragraph about the heart and great vessels, during the next five minutes the student studies a passage such as may be found in medical literature. Then for the remainder of an hour the student, working as rapidly as possible, takes six tests: (1) a scientific vocabulary test of forty items, (2) a test of premedical information (100 items), (3) a visual memory test of twenty items based on the diagram first studied, (4) a memory content test based on the paragraph first studied (twenty items), (5) a comprehension and retention test (twenty items) based on the passage in "Speech Defects," and finally (6) a test of the understanding of printed material" (fifteen items).

Dr. Robertson also touched on what is usually considered a sacred subject—personality—as well as taking a rap at subjective ratings. He indicated that even such imponderables as personality traits might one day be measured objectively and scientifically, which was most likely considered as rank heresy even eight years ago.

At the next (the forty-first) annual meeting of the Association of American Medical Colleges, Dr. F. A. Moss of George Washington University read a paper similar to that presented to the American Medical Association by Dr. Robertson, and thus for the first time the members of the association glimpsed a path out of the labyrinth in which they had been wandering for so many years. The length of the report²² and the animated discussion that followed it gave an excellent indication of the importance of the subject and the interest with which it was received. As Dr. Moss had been largely instrumental in devising the tests, his report was of much greater importance than that of Dr. Robertson. His interest was chiefly centered in the results of the testing program and he referred his listeners to the Robertson article in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* for the details of the actual tests.

The program had been put into operation in the fall of 1927 by applying the tests to the freshman class at George Wash-

ington University School of Medicine and then comparing results with the scholastic achievements at the end of the first year. Results were so generally indicative of the value of the tests that it was decided to administer them to entering students in other medical schools in the fall of 1928. Twenty-two colleges, widely separated geographically, were prevailed on to cooperate. The tests were accordingly given to the freshmen and at the end of the year the grades made by this sampling of medical students were tabulated and compared with the test scores. Even a cursory examination of the results of this comparison made it very evident that, although far from perfect, an instrument had been devised which would give a far better prediction of the ability of a prospective medical student to achieve grades of a satisfactory quality in medical school than anything previously tried out. The correlation between test scores and medical school grades for the whole group was 0.59, while in two institutions it ran up to 0.72, and in only two cases did it fall as low as 0.45.

Following this initial correlation, the test scores were then compared with various other factors and criteria in order to discover, if possible, some multiple correlation relationships that might give more reliable results. For example, the number of semester hours offered by the student for entrance to the medical school was correlated with the grades made in medical school at the end of his freshman year. This produced a coefficient of but 0.09. Grades in premedical subjects gave a correlation with freshman medical school grades of 0.50. Thus the aptitude test scores gave a superior predictive criterion for success in medical school than either of the most used criteria evolved previously.

When the aptitude test scores and premedical grades were intercorrelated with the freshman grades, a coefficient of 0.65 was the result.²³

A rather disturbing factor disclosed by the study of the test scores and grades was the wide range in the quality of the students as represented in the twenty-two institutions. Although the distribution of the grades made by the freshmen in the individual schools was practically normal, nevertheless the median scores on the tests for the men in each school ranged from a low of 94 in one to a high in another of 194, a condition which indicated, granting that the aptitude tests had a high degree of validity, that there was something lacking in the methods of choosing medical students in some of the schools.

After considerable discussion, both pro and con, of the results of this preliminary testing as outlined by Dr. Moss, the executive body of the association was authorized by the members to appoint a committee²⁴ to "direct an experimental study of aptitude tests for admission to medical studies."²⁵

Although it was fairly evident that the aptitude test was to provide the medical schools with an instrument adequate to sift the able students from the undesirables, nevertheless studies continued to be made as to other means of attaining this end, and in the July issue of the *Journal* there appeared an article by the editor²⁶ on the credentials presented by freshmen for entrance to the member institutions of the association in the preceding fall, showing the tendency of students to offer more and more academic qualifications. The author found but little correlation between the number of semester hours offered and subsequent performance in the schools, just as had been shown by the Moss report but contrary to the observations of van Beuren.¹⁰

PROGRESS OF THE PROGRAM

At the forty-first annual meeting of the association, held in Denver Oct. 14-16, 1930, Dr. Moss reported on the progress of the testing program carried on by the committee, of which he had been appointed secretary. This report²⁷ covered the testing done on the freshmen of 1929, the grades made by them at the end of their first year in medical school and also a study of the group tested in the preliminary program the previous year. Some seventy medical schools cooperated and the 1929 students were about four times as numerous as those of 1928.

Again the value of the aptitude tests was demonstrated in an unmistakable way. Grouping the students as a whole according to their aptitude test scores, it was found that there were absolutely no failures in medical school among the highest decile students in either the 1929 or the 1928 classes, while 56 per cent of the students falling in the lowest decile failed. Scholarship records in the medical school correlated with the test scores as high as 0.73 in the sophomore group in one institution, and the average for the sophomores was 0.54. This coefficient was not corrected for the improvement in the group brought about by the elimination of the failing students of the first year, and therefore the real correlation, had it been calculated, would have been much higher.

Not only were the failures ranked inversely with the decile standing of the students, but the averages of the grades of those passing their two years of medical studies were arranged in the same order as the deciles. The average of those in the highest decile was 86 per cent, while those in the lowest decile made but 75 per cent. There were of course some exceptions, but many of these were fully accounted for by some unusual individual situation. For example, low grades were noted among students working their way through college while trying to carry a full load of courses, even when they had made very high aptitude test scores. Then, too, the tests did not appear to be valid in the case of foreign speaking students.

Comparing medical school grades with premedical grades showed some positive correlation, but not as great as demonstrated by the aptitude tests.²⁸ Correlation of grades with interview ratings or personality traits was still less reliable but also was slightly positive, as was that between the number of semester hours offered by the students for admission to medical school when compared with the total grade averages.²⁹

Various combinations of criteria were again tried out, although not described at length such as premedical grades, aptitude test scores and personal interview ratings, and it was found that the combination of premedical grades and the aptitude test scores gave a predictive ratio of 73 per cent.

In passing I might note that at the same meeting a paper was presented by Robert C. Lewis of the University of Colorado School of Medicine, in which the author³⁰ went into considerable detail in explaining the scheme for admitting students to his college. It turned out to be the somewhat familiar premedical grades character-personality stuff, which had been tried and found wanting by so many other institutions. The investigator admitted that scholastic mortality among medical school students at Colorado was from 20 to 25 per cent, which did not seem to imply a high reliability for the criteria employed.

In the general discussion that followed the reading of both these papers there was much adverse criticism of the aptitude tests and much emphasis on the impossibility of choosing a doctor by means of new-fangled tests cooked up by psychologists. Also there were some remarks on the imponderability of

²³ Interpolated graphically since the figure was not given by Dr. Moss.

personality—indeed, most of the old stock objections to the scientific measurement of human nature were trotted out, but Dr Moss's impressive figures convinced almost every one, and it was apparent from the trend of the discussion that the aptitude tests had so demonstrated their value as predictive instruments that they had come to stay. Later on in the same convention the association adopted a resolution endorsing the use of the tests as an additional criterion for the selection of medical students and suggested that the member institutions make the test a normal requirement for admission,³⁰ although there is no mention of the new criteria in the official requirements for admission in the extracts from the by-laws of the association reprinted in the *Journal* at that time.³¹

The tests for 1931-1932 were carefully revised and new forms made up.³² As given in the fall of 1931 they consisted of six parts: (1) scientific vocabulary, (2) visual memory for anatomic drawings, (3) memory for descriptive material, (4) premedical information, (5) learning and retention of material and (6) understanding of difficult printed material. The whole test was to require one and one-half hours of the student's time to finish. For the first time the tests were given in colleges and universities offering premedical instruction but not having medical schools of their own—these in addition, of course, to those institutions maintaining departments of medicine. In all, 547 colleges and universities cooperated. Tests were administered to all prospective medical students, and the testing took place at the same hour³³ and on the same day, and, with the fine disregard of the scientist for common superstition, that day fell on Friday the thirteenth of February 1931.

The preliminary report covers test results of 9,220 students, a very considerable increase over previous years but considerably less than the usual number of applications received by the medical schools. As heretofore, New York and Pennsylvania lead by a wide margin all other states in the number of students seeking admission.

In the next issue of the *Journal* appeared an article by Dr W. D. Reid,³⁴ who had been one of the opponents of the aptitude testing program, in which he tacitly acknowledged the status quo by saying that selection of medical students was based on "(1) scholarship, (2) personality and (3) the aptitude test. The latter," he noted (p. 352), "is a recent method which gives promise of being very helpful."

Meanwhile, at the University of Michigan Dr C. S. Yoakum of Army Alpha fame, was experimenting with tests independently of the work of the committee of the association, and he evolved a vocabulary test and a reading test in an endeavor to predict the success of students in later medical studies. The results of this attempt were reported to the association by Miss Doris F. Twitchell.³⁵ Grades in the University of Michigan Medical School were correlated with a number of factors, such as place of residence, sex, age, institution previously attended, hours of premedical work, and premedical grades. Coefficients of correlation were not given in each case, so it is almost impossible to rank the various factors in order of their predictive value, but a study of the grade averages in

relation to the criteria would indicate that the best one discovered was the premedical grades. Even here, however, the correlation was but 0.37, which, compared with that of the medical aptitude tests devised by Dr Moss, was very low indeed. The study at Michigan was continued even though the results were so inferior.

The final report of the aptitude test committee for 1931 was made by the secretary,³⁶ Dr Moss, at the forty-second annual meeting of the association in New Orleans, Nov. 30 to Dec. 2, 1931. It was considerably longer and more detailed than any previously given on the testing program but added little except elaboration to the preliminary report published in the *Journal* at the beginning of the year.³⁷ Correlation of the test scores and premedical grades with medical school grades ran as high as 0.81 in one institution—Stanford University School of Medicine.³⁷

At the close of the report Dr Moss announced that the fourth form of the aptitude test was to be administered Dec. 11, 1931, and that there would be some changes in it from previous forms.

SEARCH FOR OTHER CRITERIA

In spite of the considerable success of the tests, a number of medical schools continued to push forward with independent studies to discover a criterion that might be more valid and reliable in predicting the success of their students. These studies were reported on from time to time, either as papers read before the members of the association in its annual meetings or in the form of articles in the *Journal*. Thus, Walter H. Moursund³⁸ read a report before the same meeting on the experiments carried on at Baylor University College of Medicine. Again it was noted that of the factors studied premedical scholarship was the best criterion on which to base prediction of achievement in medical school. He stated, however, that, although general scholarship and other factors were used by his institution as criteria of admission, nevertheless "none of these factors seemingly had a constant relation from year to year" (p. 149). Throughout the paper the absence of correlation figures makes comparisons difficult if not impossible.

Chicago, too, was carrying on experiments with selective criteria on which to base their choice of students for the medical schools of the university, and W. F. Cramer, statistician in the office of the registrar, wrote a report³⁹ on the results. A study of the students enrolled in 1918, 1919 and 1920 was made, which included 294 cases, and various factors which might affect scholarship in the medical school were carefully weighed and correlated with one another. For example: 1. The relation of success in the medical schools to the age of the student at the time of entering. It was found that while there was some indication that the more mature student would achieve better success, nevertheless the correlation with age was so small as to be practically negligible. 2. The relation of scholarship in premedical courses to success in the medical schools. Here appeared the best correlation obtained, 0.53 between medical grades and the total premedical program and 0.38 between grades and the natural sciences taken as premedical subjects. Correlations for students taking both medical and premedical work in the university ranged from 0.76 to 0.56 when calculated for the relationships previously mentioned. 3. No significant relation was found between the type of institution previously attended and success in medical school, except for those taking all their work at Chicago. 4. The amount of

36 Moss, F. A. Report of the Committee on Aptitude Tests for Medical Students, *J. A. Am. M. Coll.* 7: 129-141 (discussion pp. 141-148) (May) 1932.

37 The correlation of the other extreme is not given.

33 It is not stated whether the hour was solar or standard time, but since the schools were spread over a wide area from Maine to Hawaii with a standard time difference of six or seven hours it is quite probable that it was standard time. Hence the insistence on having the students take the tests at the same hour seems to have little real sense behind it.

34 Reid, W. D. Premedical Education, *J. A. Am. M. Coll.* 6: 345-356 (Nov.) 1931.

35 Twitchell, Doris F. Report of Data Pertinent to the Problem of Selection of Medical Students, *J. A. Am. M. Coll.* 6: 357-361 (Nov.) 1931.

academic preparation also proved to have but little relation to medical school success. In other words, the only criterion discovered that was worth anything was scholarship in premedical courses, and this alone did not produce particularly high correlation coefficients, with the exception of those students who did not transfer from one institution to another.

It seems to be rather significant that from this time on less and less is to be heard of the aptitude tests for medical students. True, Dr. Moss⁴⁰ continued to give his report to the association year by year but the high correlation with the tests and success in medical school compared with the much lower correlation with other criteria and tests, and the still greater correlation produced in conjunction with the premedical grades, eventually seems to have convinced practically all members of the association of their sound worth and opposition to them dwindled at a steady rate.

Since the 1932 tests were to be administered in December 1931, several months earlier in the year than previously they were altered to compensate for the lesser amount of knowledge of premedical matters possessed by the student. Another change was the addition of another part—ability to follow directions. Changes introduced from form to form were slight and in general merely followed new developments in psychology and educational testing techniques. For example the alternative choice type of question was considerably reduced in number in favor of matching forms of questions. The pre-

*Proportion of Applications to Applicants**

* Calculated from data on page 66 of the second report.

medical information part was dropped since it had been decided that a combination of the aptitude test and premedical grades gave the best criterion of success in medical school, and the premedical information part was merely a test of the same factor. In its place was substituted a medical vocabulary test that seemed to have a high selective value.

A mild revolt against the tests took place at the 1932 meeting of the association led, strange to say by Dr. E. B. McKinley, dean of George Washington University School of Medicine the institution that might be termed the birthplace of the whole testing program. The uprising was very feeble and ill sustained and seems to have been based on the theory that correlations of from 0.50 to 0.65 were practically useless for predicting success in medical schools and it quite ignored the fact that there was nothing better available and that a selective criteria was in greater need than ever, for Dr. Zapffe's reports showed that, while the number of applicants and applications for admission to medical schools showed a slight decrease, which was due no doubt to the depression, the number of credits offered for admission, that is, the qualifications of prospective students, was steadily rising, and the number of multiple applicants in proportion to the number of applicants was also continually increasing.⁴¹

The fruits of the aptitude testing program had already begun to be apparent in 1932, as was shown in a report by Dr. Zapffe, in which he noted a distinct decrease in the scholastic mortality of freshmen in both 1930 and 1931,⁴² although, strange

to say, he does not appear to see the causal relation, for he asks oratorically: "Can this be charged to better preparation for the study of medicine?"⁴³ Mortality for 1932 was once what higher than in 1931 but still considerably below the average of preceding years (p. 160).

In 1934 a special committee was appointed by the association to study the tests and to deliver a report at the next meeting, the forty-sixth, held in Toronto Oct. 28-30, 1935. The report⁴⁴ was presented by the chairman, Alan M. Chester, and covered tests administered to 6,000 students in various schools all over the United States, as well as an intensive study of a random sampling of 800 students. Special investigations of several individual institutions were also made.

The report went into the broader aspects of the testing program and dealt very fully with the difficulties and shortcomings of such an ambitious undertaking concerning as it does a large number of students scattered over a wide geographic area and varying greatly in ability, education, background and motivation. It was found that some schools in the more thickly populated parts of the country were able to choose their students from among those in the higher brackets of the aptitude test scores while others were more or less forced to admit students from a much wider range of scores. This difference tended to produce a lower correlation since there is always a very strong tendency for grades in any subject to be grouped according to the normal curve. Thus in one school all failures might occur in the 50-75 percentiles there being no students admitted below the fiftieth while in another institution those students in the 50-75 percentiles might conceivably be rated A if there were few or none coming from the upper quartile of the test scores. In this way the tests would be blamed for a fault that was not inherent in them but in their application by the various schools.

The committee decided that the value of the tests depended on the way in which they were used. In good hands the results were distinctly beneficial.

CONCLUSION

Though has been written perhaps to prove that the aptitude tests have gone a long way toward solving the problem of selecting applicants to medical schools. Each school, at present is of course a free agent in choosing the students to fill the limited numbers of its student body, but it would appear that a better method would be to restrict admission to any school to students scoring above the median, and to promote these superior individuals to the various colleges of medicine. However such a regimentation would raise a tremendous protest from the rugged individuals, both on faculties of medicine in the profession, and in the ranks of the students themselves. Meanwhile, the public will have to suffer when the incompetent medical student finally emerges from his internship and begins to practice in more than one sense of the word.

Two problems suggest themselves from this survey of aptitude tests applied to a particular field. First, the possibility or even certainty that correlations of a fairly scientific instrument such as the medical aptitude test with the more or less haphazard and almost wholly subjective grades given out by the average college and university instructor, are much lower in many cases than they would be were medical grades based on subject tests standardized for the whole country. This would probably do away with the complaints of high aptitude test students being given low grades in one school and the

opposite state of affairs in another. Thus the development of standardized tests in medical subjects should be promoted.

Perhaps the more serious problem is the second one suggested, that is, the relation of test scores and medical school grades to the excellence of the finished product of the medical school. It does not necessarily follow that the 98 percentile, A student from a class A school will become a successful practitioner, and so far no one seems to have any instrument of predictive value adequate for this task. The profession and the public wait for some one to evolve a measuring stick which will, when laid on the stream of consciousness, to paraphrase William James, say 'Here is another Hippocrates, Harvey, Osler, or even perhaps Mayo.' We also await the millennium 1035 East Sixtieth Street

Book Notices

Your Hay Fever By Oren C Durham Chief Botanist Abbott Laboratories North Chicago Illinois With an Introduction by Morris Fishbein and a chapter on Treatment by Samuel M Feinberg M.D. F.A.C.P. Cloth Price \$2 Pp 264 with 19 illustrations Indianapolis & New York Bobbs Merrill Company 1936

While this book is written primarily for the layman, and especially for the two million or more in this country who are affected by hay fever, its wealth of material should likewise appeal to the general practitioner. The author, a botanist, has been associated for the past twenty years in the research work of some of the pioneers in allergy. His chief contribution in recent years has been the organization of a national pollen survey with numerous stations for daily atmospheric studies throughout the country. The style with which the material is presented is narrative with subtle humor, which adds to the zest and helps maintain the interest. The first hundred pages is devoted to a historical outline of the research that led to our present conception of hay fever, with special emphasis on the discovery of the relationship of air-borne pollens to the symptoms. Blackley's research work is presented in detail. The development of our present method of hyposensitization by pollen injections is treated much too briefly. The arrival at our present understanding of anaphylaxis is hardly mentioned. The work of Richet and Portier, of Theobald Smith and Pirquet is omitted, probably to avoid confusion in a work written for the layman and limited to pollinosis. In the second hundred pages the author gives the history of pollen surveys, the methods used, the results of such studies, and the relationship of tree, grass and weed pollens to symptoms. Present methods of treatment are discussed in the last fifty pages. Dr Feinberg devotes about half of this space to an excellent discussion of hay fever resorts. His table showing the atmospheric pollen studies in these is of value as an index of the degree of relief to be expected in each. The book gives a clear, intelligent presentation of the history, research and treatment of hay fever. Written primarily for the layman, its wealth of material makes it valuable also for the general practitioner.

The Treasury of Human Inheritance Edited by R. A. Fisher F.R.S. Galton Laboratory University of London. Volume IV. Nervous Diseases and Muscular Dystrophies. Part II. On the Peroneal Type of Progressive Muscular Atrophy. By Julia Bell M.A. M.R.C.P. Paper Price 12s. 6d. Pp. 140 with illustrations. London: Cambridge University Press, 1935.

A valuable service both to medical men and to those interested in genetics has been performed by the Galton Laboratory of the University of London in compiling the series of publications known collectively as the 'Treasury of Human Inheritance'. The study on the inheritance of peroneal atrophy brings together a large amount of material and crystallizes knowledge concerning the heredity of this interesting malady. The age of onset was found by Bell to vary widely each affected family providing a study in itself and tending to have its individual characteristics from the point of view of clinical symptoms resulting disability and age of onset. It is interesting to note that individuals of the same sibship tend to be affected at about the same period, often in the same year of life. Attention is called to the fact that in some cases the first symptoms may be noted in the hands or even in all four extremities at the same time, although in the majority of cases the lower extremities are involved first. The signs and symptoms of the disease are adequately described and illustrated by photographs of patients, and there is an interesting chapter on the association of peroneal atrophy with other inherited defects. A brief chapter on the pathology of the condition adequately sums up all that is at present known of this subject. Bell states that consideration of a number of family studies indicates that peroneal atrophy is definitely inherited in different families as a dominant, a sex-linked recessive, and possibly also as a simple recessive, although some of the pedigrees are admittedly difficult of interpretation. Statistical data and various correlations are well presented in tabular form and a number of interesting pedigree plates of affected families gathered from the literature and from personal observation are appended to the monograph together with a satisfactory description of each family. An interesting point brought out in this study is the apparent linkage of peroneal atrophy with inability to taste phenylthiocarbamide in one family. Unfortunately, no definite conclusion could be reached but further investigation along similar lines is desirable, since clear demonstration of the linkage of a disease of this sort, which is not present at birth, with some congenital anomaly, may supply a valuable aid to prediction concerning the liability to manifest the inherent hereditary defect.

Out of the Night: A Biologist's View of the Future By H. J. Muller. Professor of Zoology University of Texas. Cloth. Price \$1.50. Pp. 127. New York: Vanguard Press, 1935.

The author of this small but potent book is one of the world's leading geneticists. He has been on leave of absence from the University of Texas for several years and has been senior geneticist at the Institute of Genetics, Moscow. The title of the book carries the implication that humanity is emerging from the darkness of ignorance as to the mechanics of human evolution and is now in a position to direct the course of its own future evolution. Muller attempts to predict the future of man under a managed program of progressive eugenics. He regards mere negative eugenics (the segregation or sterilization of the unfit) as unlikely of itself, to advance the status of the race. The only real advance in human evolution is one that would result from breeding extensively from the best human types. There is no good reason why a very exceptional male could not furnish enough male gametes to fertilize thousands of human ova. There is also no technical difficulty about artificially inseminating ova. In reply to the criticism that it would be difficult to decide which are the most superior men while they are still young and sexually active, it is advised that the seed be kept alive for twenty-five years while the evaluation of a man's genetic worth is being made. Selection should be based apart from physical vigor and well being, on two essential qualities: social sense (comradeliness) and intelligence. Certain secondary difficulties with this proposal suggest themselves. What about love and marriage? Muller would separate sexual love from reproduction by the practice of birth control methods. He also regards his plan totally unfeasible in a democracy such as the United States for the popular judgment as to the eugenically superior men would doubtless favor a race of Billy Sundays, Babe Ruths, Valen-

tinus, Jack Dempseys, or even Al Capones. Only in a fully integrated socialistic country could progressive eugenics be practiced for, where environmental conditions are the same for all genetic differences would reveal themselves for what they really are. Muller's ideas as to the possibilities of progressive eugenics in so short a time as a paltry century or two is given in his own words: "It would be possible for the majority of the population to become of the innate quality of such men as Lenin, Newton, Leonardo, Pasteur, Beethoven, Omar Khayyam, Pushkin, Sun Yat Sen, Marx, or even to possess their varied faculties combined." "How many women, he says in another connection, 'in an enlightened community devoid of superstition, taboos and sex slavery would be eager and proud to bear and rear a child of Lenin or of Darwin!' This book is extremely well written. It is the vision of a geneticist convinced that what has been found true for the fruit fly is surely applicable to man. In other words the book is an excellent exposition of the extreme hereditarian doctrine as held by most modern geneticists.

Histochimie animale. Méthodes et problèmes. Par L. Lison, assistant à l'Université de Bruxelles. Avec une préface de M. Pol Gerard. Collection des actualités biologiques sous la direction de M. Robert Lévy. Paper. Price 70 francs. Pp. 320. Paris: Cautliet Villars, 1936.

This is a critical and lucid exposition of the chemistry of tissues as studied in microscopic sections. The first part takes up the general methods and limitations. In general substances in solution in cells cannot be localized because they diffuse during analysis and substances not in solution may be extracted by preliminary treatment. Therefore the most general method is freezing the tissue. After it is once frozen there are two main methods of treatment. It may be dried without thawing. If paraffin soluble substances are not to be analyzed it may be impregnated with paraffin in the dry state and cut into sections and mounted on slides and if only inorganic substances are to be studied the slide may be heated in a muffle furnace so as to ash the section and then the ash analyzed by various methods. Another method is to cut frozen sections and place them on slides before they thaw. Except when the tissue is dried, some form of fixation is often necessary but fixation has to be adapted to the later process. In general the use of aniline dyes cannot be considered chemistry and heavy metals give reactions that are specific only under exact conditions. The sensitivity is usually one hundred million million times that of ordinary chemical sensitivity and limitations are given in fractions of a microgram. (Results are qualitative not quantitative.) The chemical analysis of sections includes: 1. Solubility, but it should be remembered that mixtures may have solubilities different than the pure substances. 2. Microspectroscopy and this may be done on the native substance with either visible or ultraviolet rays or by means of a high frequency unpolarized spark spectrum immediately above the section. In this case the limitation of area is relatively large but less than 1 mm. in diameter. 3. Microfluoroscopes. (Substances emit light of a longer wavelength than the incident light. The usual incident wavelength is 3660 angstroms.) 4. Polarized light for the study of crystals. The second part of the book enumerates the special analytic procedures for different substances, with sections on minerals, proteins, lipids, glucides, pigments, ferments and vitamins. The image of the ash of a section is called the spodiogram, but iron is the only colored element that is of great enough concentration to be detected by the microscope without reagents. All other elements must be studied by means of microreactions and the use of microscopic drops of reagents. Elements can be localized in cells only when combined with the protein skeleton and then are in a condition called 'masked' and must be liberated by micro incineration or other methods. The proteins are mostly localized, and color reactions for amino acids can be used in the microscope. Also they may be digested. There are ways of distinguishing scleroproteins. Substances with a benzene ring are especially studied and the chromaffin reaction for epinephrine is explained. The argentaffin reaction is shown to be of histologic importance but not always of chemical specificity. As it is used to diagnose rickets, it is not chemically specific. Nucleoproteins may be studied with the murexide and other reactions. Fats may often be fixed with heavy metal oxides, and a table of analysis of lipids is given. Fixed lipids are considered lipoprotein compounds.

Glucides include glycogen, and the chromotrope reaction for the scleroproteins containing sulfuric acid. Pigments may be studied by their own color, and the derivatives of hemoglobin are studied with chemical reactions, the porphyrins being studied by fluorescence. Of the ferments the peroxidases and phenolases (oxidases) are detected but their biologic significance is doubted. Melanin formation is considered as due to the tyrosinase and dopa oxidase. Of the vitamins, only vitamin C is studied. It reduces silver nitrate instantly, whereas epinephrine does so only slowly.

DeLafield and Prudden's Text Book of Pathology. Revised by Francis Carter Wood M.D. Director of the Pathological Department St. Luke's Hospital New York. Sixteenth edition. Fabrikoid. Price \$10. Pp. 1406 with 881 illustrations. Baltimore: William Wood & Company 1936.

This book was first published in 1885 and at that time it was the first important textbook of pathology in America. The fact that the book has passed through sixteen editions shows the popularity of the work during half a century. The present edition is handsomely bound and contains a wealth of pathologic material useful to pathologists, medical students and physicians. Criticism of such a book is difficult; certain suggestions appear indicated however, despite the glories of the past. Dr. Wood says in the preface: "Many requests have been received by the editor to render the book more modern but unfortunately modernity is largely only a changing of the labels on the specimen bottles." This attitude allows no place for the existence of ideas, and pathology and its concepts have developed considerably since 1885. As a matter of fact, the best chapter in the book is the one by Deery on the nervous system, and it is good because it is modern. The editor remarks that "the book has already reached the limit for comfortable handling in attempting to cover incompletely the subject with which it deals and any increase in size is therefore prohibited." Why not eliminate a lot of the obsolete historical material and allow space for more important pathologic material? Why carry the pictures of cell division on pages 82-85 in this day of sound biologic training of medical students? Why retain the old "side-chain" pictures of Ehrlich and the old pictures of bacteria with the obsolete bacteriologic descriptions accompanying? Modern students must be annoyed by such antiquated material as, for example, figure 107 showing a sterilized cotton swab in a sterilized culture tube. Why discuss the incidence of cases of peptic ulcer with a reference of 1885? Many pages could be saved by elimination of this obsolete material. Furthermore, many old labels should be changed. The discussion on yellow fever refers to *Leptospira icteroides* as the cause and makes no mention of the enormous amount of work on the virus relationship. The use of congo red in association with amyloid disease is not mentioned. Many other objections might be cited, but perhaps enough has been said to indicate that the book needs real revision rather than rebinding. There is too much looking backward with the retention of material which really belongs in a history of pathology. Ideas still remain the important features of pathology.

Le diabète sucré. Questions controversées de clinique et de pathogénie. Par P. Mauriac et al. Leçons professées à l'Hôpital Saint André de Bordeaux (Service du Professeur P. Mauriac). Paper. Price 32 francs. Pp. 213. Paris: Masson & Cie 1935.

This is an interesting volume by several authors dealing chiefly with the controversial problems in the field of diabetes. The hepatomegalies of infancy and the metabolism of carbohydrates are taken up in the first chapter together with the differential diagnosis from the von Gierke disease in its primary disturbance of carbohydrate metabolism. In these there is an enlargement of the liver without splenic enlargement which liver enlargement the authors consider one of pluriglandular type, chronic in nature and allowing a long survival. Diabetic comas without acetonuria are taken up next. These are seen exceptionally. The considerations in this group are largely of a theoretical nature. The reaction toward insulin in the juvenile group of patients with diabetes is taken up next: the insulin resistant and the insulin sensitive. These two groups are thought to be radically different basically. It is possible that there are two mechanisms at play. In the insulin sensitive cases the author considers that it is not merely the insulinogenic function alone but rather a difficulty of a pluriglandular nature,

the equilibrium between the glycoregulatory mechanisms being disturbed. This could be caused by a disturbance of the vagus, which affects the secretion of insulin, or of the splanchnic, which affects the secretion of epinephrine or by dysfunction of the pituitary, which has to do with the regulation of the blood sugar. The intermittent type of diabetes is taken up next, which the authors consider chiefly as of endocrine, pluriglandular type. Nervous complications of diabetes are illustrated by case histories. The authors consider these as expressing the duality of diabetes and being due to many other factors. The eye complications, according to the author's view, come not from the diabetes itself the underlying factor being nephritic. The treatment of this condition as well as diabetes is in order. The chapter on examination treatment during illness and the follow up of the cases is discussed along general lines. The individualization is emphasized. The chapter on insulin by Professor Aubertin is discussed at great length historically and physiologically. The question of blood sugar and its behavior in various types of individuals is considered in the last chapter. The authors show the basic differences in the pyknotic, the athletic and the leptosomic types. In the pyknotic the curve rises considerably, lasts for a time and descends gradually, in the athletic type the fall of the curve is quicker, in the leptosomic type the curve is less elevated than in the preceding and its descent is more rapid. On the whole this volume covers the less known and usually considered phases of the diabetic problem as dealt with in ordinary publications on diabetes and will be a great help to students. It emphasizes the pluriglandular factors.

The True Physician. The Modern 'Doctor of the Old School.' By Wingate M. Johnson M.D. Cloth. Price \$1.75. P. 157. New York: Macmillan Company 1936.

Dr. Wingate M. Johnson is one of the most popular writers in our profession. He has the fortunate faculty of being able to interpret the problems of medicine to the physician and to the layman as well. He has had a long and successful experience in practice and with this background he writes this book for young physicians and undertakes to give them "some fatherly advice on what their conduct should be during the early days of practice." The book is comprehensive. Its advice and suggestions cover the subject in minute detail, from office equipment, dress and manners and social habits to habits of work and study, marriage and religion. He does not hesitate to offer suggestions about the banalities of professional life which are so important and which are likely to be thought beneath consideration. His topic is really the practical factors of medical success and the advice which he gives is good. It is given from the standpoint of worldly wisdom, but it is genuine and frank and stimulating. Dr. Johnson has that unusual sort of personality which combines practical common sense with idealism, and these qualities show through the book. It has many useful suggestions for young physicians and not a few for the older ones.

Clinical Diagnosis of Diseases of the Mouth. A Guide for Students and Practitioners of Dentistry and Medicine. By Louis V. Hayes A.B. DDS. Associate Professor of Oral Surgery and Lecturer on Diseases of the Mouth New York University College of Dentistry. With an Introduction by Leo Winter DDS M.D. Sc.D. Professor of Oral Surgery New York University College of Dentistry. Cloth. Price \$7.50. Pp. 481 with 365 illustrations. Brooklyn: Dental Items of Interest Publishing Company Inc. London: Henry Kimpton's Medical Publishing House 1935.

This book is designed "to serve students and practitioners of dentistry and medicine as a practical aid in their special and common endeavors respectively to prevent and cure diseases of the mouth through the development of skill in oral diagnosis." In the introductory chapters there is appropriate emphasis of the close relation between oral and general pathologic changes which dictates a very careful appraisal of both local and general systemic observations. Significant items for consideration and record in examination are carefully outlined. These chapters are followed by discussion of a comprehensive list of diseases that contribute oral lesions. Objective subjective and laboratory elements in diagnosis are considered, with frequent illustration of gross and microscopic tissue changes. Each entity is discussed under the headings of definition, etiology, symptomatology and treatment. There is perhaps some weakness with respect to differential diagnosis. Comment under the

sections devoted to treatment is terse and practical, which adds to the clinical value of the book but should be considered as a suggestion or preface to further investigation by the student or practitioner rather than as a basis for therapy. This is undoubtedly why the author did not include the subject in his title. The arrangement of material is explained in the final chapter, where it is stated that the grouping of lesions and diseases of the mouth was planned particularly for teaching purposes, beginning with the more common conditions and progressing to those presenting greater difficulty in diagnosis. This has resulted in some confusion, as neither purely topical nor strictly pathologic criteria are maintained. It offers certain advantages as a textbook, provided the course of study is planned with the grouping in mind. Where the topical arrangement is followed the practitioner will find that it facilitates reference, as for example in the chapters 'Cheek Lesions' and 'Lesions of the Palate'. There are inconsistencies however as exemplified by placing hemiatrophy of the face under 'swelling of the face,' osteomyelitis under 'oral fractures' and supernumerary, impacted and fused teeth under 'cysts of the jaws'. There are seventy-nine pages of bibliography grouped with respect to the chapter titles and subdivided with regard to book and periodical literature. In this respect as well as in the listing of a summary of the significant features in the disease entities discussed, the text should be of practical value.

A Guide to Human Parasitology for Medical Practitioners. By H. H. Blacklock, M.D., D.P.H., D.T.M., Professor of Tropical Hygiene, Liverpool School of Tropical Medicine, The University of Liverpool and T. Smithwell, D.Sc., Ph.D., A.R.C.S., Walter Myers, Lecturer in Parasitology, School of Tropical Medicine, The University of Liverpool. Second edition. Cloth. Price \$4. Pp. 259 with 124 illustrations. Baltimore: William Wood & Company, 1933.

The second edition of this primer is in itself an index of the success of the original volume which appeared in 1931. The guide is a brief but comprehensive outline covering the general field of medical parasitology: the spirochetes, the human protozoa and helminths and the problem of myiasis. In addition there are short chapters on the microscope, the technique for diagnosis, a list of necessary reagents and apparatus and a list (entirely too short) of the more important comprehensive textbooks and manuals on the subject. Likewise there are tables listing the geographic distribution of the human helminths, the sources of infection for several of the parasites, intermediate stages and hosts of the organisms and a summary diagnostic table. One page contains a pictorial representation of the eggs of helminths and sixteen pages are devoted to diagrammatic representations of the life cycles of the more important animal parasites. For each important infection the geographic distribution, habitat in the human body, morphology and life cycle of the etiologic agent, pathogenicity and diagnosis are briefly outlined. Symptomatology, treatment and prevention are unfortunately not considered and this constitutes the only major criticism of this concise volume. In a future edition less space might well be given to tables, the chapter on the microscope omitted, and some space provided for the applied aspects of the subject, which are all important for 'medical practitioners'. The terminology is modern except for *Dibothriocephalus latus*, which is used instead of the approved designation *Diphyllobothrium latum*. The information included has been brought down to the date of publication. The illustrations, including two colored plates, are clean cut and well chosen, and the technical and typographic errors are very few. The volume is splendidly printed.

El dinitrofenol 1,2,4 estimulante del metabolismo y sus aplicaciones clinicas. Tesis de Efrén Carlos del Pozo. Universidad Nacional de México. Facultad de medicina. Paper. Pp. 203. México D. F. A. Vilares y Hno. Impresores. 1935.

This doctorate thesis contains the most complete and critical survey of the voluminous literature on dinitrophenol that has yet appeared. The author reviews the history of the industrial use of the compound and related dyes, and its toxicologic importance during the war. Then he describes the pharmacologic studies of it in the United States and France and from these develops the ideas of the possible clinical uses of the drug. The indications, contraindications and methods of administration are treated in detail, summarizing the entire published work in these topics. He gives his personal results in thirty-

two cases of obesity, of which thirty were satisfactorily treated with this drug. An average loss of weight of 458 Gm a week was secured on doses of from one to four capsules of 0.1 Gm daily. The only side actions observed were two cases of pruritus, there being no leukopenia, cataracts or other serious sequelae in this series. The author reviews the cases of poisoning reported in the literature and points out that in practically every such case either the dosage taken was excessive or it was increased too rapidly, or there were other contributory conditions more important probably than the dinitrophenol. His critical evaluation of the published reports and his own experiences permit him to conclude that, in agreement with Trautner and his colleagues, he believes dinitrophenol to be a powerful and effective remedy for use against various forms of obesity, and especially those cases in which simple, less drastic measures are ineffective.

The Cranial Muscles of Vertebrates. By F. H. Edgeworth, M.D., M.A., D.Sc. (1911). Price \$30. £5 5s. 1p. 493 with 811 illustrations. New York: Macmillan Company, London: Cambridge University Press, 1934.

This book is a painstaking scholarly and exhaustive study of one phase of animal evolution. It presents the work done by the author over a period of many years and it includes the similar work of the last two centuries on cranial muscles and the lower neurons that innervate them. It covers all the vertebrate phyla and deals with both the structure of the adult and the developmental history. It throws light on the real character of these structures and on their phylogenetic history. It is necessarily a large book. The illustrations cover 193 pages and are systematically arranged from the lowest vertebrates to man. It is a scholarly work covering a difficult field. The infinite mass of material representing the tentative experiments of nature contains the story of the evolutionary origin of head muscles. But to read that story is so difficult that few have tried. Few could see the homologies of the muscles and nerves concerned and few could have had the insight and patience to select from the myriad names those which express true homologies. All this has been done but it is not surprising that the author has found a table of synonyms necessary to enable readers to profit from the order which he has introduced into the chaotic mass of names. Some of the conclusions are interesting. In some unknown way the growing organism appears to foresee future needs and sets to work with such material as it has to develop the necessary structures along the lines followed by its ancestors. Animals are psychological units characterized by memory and purpose, striving after ends in view—this psychological factor is of great importance from the very first. This immaterial, non-spatial teleological factor, the mind can initiate and inhibit physico-chemical processes. Life development and evolution are primarily due to this power. Whether biologists agree with these views or not, they will be a unit in their gratitude to Dr. Edgeworth for setting in order and permitting some understanding of an intricate mass of biologic facts.

An Outline for Students on Diseases of Nose, Throat and Ear. By Hugh Gibson Beatty, Ph.D., M.D., Professor and Chairman, Department of Oto-Laryngology, College of Medicine, The Ohio State University. Lectures on Bronchoscopy and Esophagoscopy, Harelip and Cleft Palate and Postoperative Care of Surgical Cases. Bards. Price \$3. Pp. 91 with illustrations. Columbus: The Ohio State University, 1936.

This outline is what it claims to be: a guide for students. In brief form with short sentences and phrases, it is an excellent aid to the individual taking the required courses in ear, nose and throat. There are a number of good illustrations of the anatomy of the various regions discussed. Within its limitations, this work can be highly recommended.

Neurologie. Par R. Monier-Vinard, medecin de l'Hôpital Ambroise-Paré. Collection des Initiations médicales publiée sous la direction de Dr. A. Sézary. Paper. Price 22 francs. Pp. 222. Paris: Masson & Cie, 1935.

This is one of a series of short volumes, 'Collections des Initiations médicales' published under the direction of Dr. Sézary. It is an excellent introduction to clinical neurology, giving directions for the examination of patients, description and explanation of symptoms and signs, and description of the chief syndromes. Individual diseases are not taken up. It is written in a delightfully clear, concise and logical French style.

Miscellany

STEPHEN J MAHER OF CONNECTICUT

A Record of Enthusiasm Beyond Judgment in the Treatment of Tuberculosis and Asthma

In November 1933, newspaper headlines again shrieked a new discovery for killing tubercle bacilli in vitro. Dr Stephen J Maher, in an address before a group of Connecticut physicians at the Laurel Heights Sanatorium, had been the source of these reports. Thus the New York *Herald Tribune* headlined its item "New Path to Tuberculosis Cure Is Announced by World Expert", the New York *Times* said "Tubercular Germ Killed by Bacterin Bred by Dr Maher", the Chicago *Tribune* "Finds a Serum That Destroys Phthisis Germ" the Milwaukee *News* "Tuberculosis Cure Believed Found". Many other similar reports appeared, some expressing doubt as to the conclusions drawn from the work reported. Then the furor and the tumult died until May 1935, when a new batch of newspaper articles appeared. This time it was a cure for asthma developed by Dr Maher. In the New York *Times* the headlines read "Physician Reports Cure for Asthma. Dr S J Maher Asserts Dead Progeny of Avian Tubercle Bacillus Has Stopped Disease—Offers It to Any Doctor—Tells Norwich Parley It Aided Epilepsy Cases—Academy Awaits His Proof". The *Drug Trade News* for May 27, 1935, stated that representatives of two large New York drug houses had offered Dr Stephen J Maher of New Haven, chairman of the Connecticut Tuberculosis Commission, \$50,000 if he would patent and sell to them his process for making the bacterin obtained from the dead "progeny of the avian tubercle bacillus" with which Dr Maher stated that he had cured hundreds of cases of asthma. He replied, according to the report,

I could use advantageously \$50,000 in my laboratory work but I have decided that the wiser way will be to tell the world what I now tell you about the composition of the bacterin the method of preparing it and the results of using it.

In March 1935 an article was published under Dr Maher's name in the *American Review of Tuberculosis* entitled "The Progeny of the Tubercle Bacillus". In brief, this article stated that he had been 100 per cent successful in transmuting six strains of tubercle bacilli into cocci and diplococci which in many ways resembled the pneumococcus. The resultant cocci and diplococci multiplied rapidly and produced an acid which was harmless to themselves but usually destructive to the remaining tubercle bacilli. "The treasured secrets" of his work were communicated to three physicians, who, according to newspaper reports, also succeeded in breaking down strains of tubercle bacilli into cocci and diplococci. He stated at the end of his communication that he had not yet secured any convincing evidence from animal experiments that these cocci and diplococci had any preventive or curative effect on tuberculosis in guinea-pigs or rabbits. There was abundant evidence, he stated, that these cocci and diplococci, whether derived from avian, bovine or very pathogenic human tubercle bacilli, produce no harmful effect when injected into guinea-pigs or rabbits.

Up to this time, no report has appeared in a scientific journal from Dr Maher embodying the work leading up to the asthma cure. The only available literature on this subject is a mimeographed report of a paper presented before a state tuberculosis conference at the Sanatorium Uncas-on-Thames, Norwich Conn., May 16, 1935. This was entitled "The Scientific and Clinical Importance of the Progeny of the Tubercle Bacillus".

The treatment for asthma apparently originated as follows. A flask of glycerin broth culture of a non-acid-fast avian tubercle bacillus was put aside at room temperature for a week. When examined at the end of this period the non-acid-fast bacilli had disappeared and had been replaced by small yeastoid masses of acid-fast coccoids and short bacilli in fields of non-acid-fast cocci and diplococci. For the sake of brevity, he says "I named the content of this flask A.Y. indicating Avian Yeastoids". All the subcultures from this flask had the same microscopic appearance, and none were found harmful when injected either alive or heat killed into guinea-pigs or rabbits.

He prepared a "bacterin" from a glycerin broth culture of this A.Y. for use in some of his "sickest private tuberculosis patients". Most of the patients were little affected, but a small proportion improved in every way. The most striking improvements, he believed, occurred in those patients whose tuberculosis was complicated with symptoms of bronchial asthma. He has therefore in recent years used A.Y. in the treatment of asthma only. "For asthma of all kinds it is the most efficient treatment of which I have knowledge. It has cured where all kinds of injections have failed. It has cured in a few days scores of cases of asthma of twenty years duration. It has cured in *one day* [italics ours] cases of asthma in children which the most famous asthma specialists in Boston and New York had pronounced incurable. It cures promptly asthma caused by hay fever, so called 'horse asthma', 'cat asthma', 'dust asthma'. He has never administered A.Y. by hypodermic or intravenous injection. There follow in the mimeographed report referred to a considerable number of case reports. He states that he has also used A.Y. successfully in the treatment of epilepsy, chorea and dementia praecox.

The public announcements already described produced a tremendous number of inquiries to medical societies and apparently to Dr Maher direct. The reply made to the inquiries to him by patients was as follows:

Dr Maher makes no claim that the bacterin he uses in his own practice will cure every case of tuberculosis. However if the physician under whose care you now are will write to Dr Maher describing briefly your case and indicating a desire to use the bacterin agreeing to keep Dr Maher informed as to your progress Dr Maher will forward to your physician a small amount of the bacterin for your use.

SECRETARY TO DR MAHER.

This apparently agrees with the experience of one patient who wrote directly to Dr Maher in response to the newspaper publicity of the fall of 1933. This patient was unable to convince her physician that she should have the oral bacterin, but she was able to persuade a retired physician to write to Dr Maher, asking for the preparation. His reply to this patient was:

I was very much pleased today to receive a letter from Dr _____ asking me to send the bacterin to you and promising to supervise its administration and to keep me informed as to your progress. Therefore I am sending four bottles of the bacterin by today's mail. I enclose herewith the directions for taking the medicine. Keep the little brown bottles in a dark place, a bureau drawer for instance. I expect that your gentle persistence and your faith will be rewarded by a prompt cure. Kindly notify Dr _____ when the little box arrives.

This patient reported that she did not pay for the medicine. According to her report, she had her first chest roentgenogram about four months after she had started taking the medicine, which showed, she stated, a normal right lung but cavities in the left lung. She stated that her sputum had never been examined and that she coughed a great deal and had a midday rise in temperature. She was apparently not being examined by a physician and stated that her only contact with a physician was in asking him to notify Dr Maher when her supply of medicine was exhausted.

The treatment of asthma with A.Y. also resulted in a large number of inquiries by laymen and physicians apparently both direct to Dr Maher and to medical societies. In one available response to the direct inquiry of a patient the following was sent: Dr Maher will send the medicine to your physician, provided that he writes to Dr Maher, asking for the medicine, and giving the history of your case and promising to keep Dr Maher informed as to the progress of your case. Dr Maher's fee for sufficient medicine for four weeks supply is ten dollars, signed by the Secretary to Dr Maher. It is evident therefore, that while apparently no fee was charged for the material used in tuberculosis a fee was charged at least part of the time when the remedy was employed in asthma.

Dr Stephen John Maher was born in New Haven Conn., in 1860 and was graduated by Yale University School of Medicine in 1887. He has been for many years a Fellow of the American Medical Association specializing in tuberculosis and he holds membership in the Society of American Bacteriologists. Since 1911 he has been a member of the State Tuberculosis Commission in Connecticut, and, since 1913 its chairman. In 1915 he was president of the New England Conference on

Tuberculosis and during the same year president of the Connecticut State Medical Association. He has also received the Laetare medal of the University of Notre Dame. Obviously the work of an individual of such standing is bound to attract national attention and, for this reason he carries a responsibility far beyond that carried by the average man. The Journal feels, therefore, somewhat reluctant about calling attention to the fact that the remedies now being sold by Dr. Maher directly to patients, according to the evidence available have not been standardized, the remedies are sold to patients largely by correspondence, without any indication of careful medical supervision, and at least one patient has been told that the medicine is likely to bring about prompt cure notwithstanding the fact that such evidence as is available concerning its virtue is to say the least highly doubtful. Physicians who specialize in tuberculosis know, of course that there is nothing new in the observation of degenerative or mutation forms of this organism. There have been innumerable previous descriptions of microscopic forms which in no way resembled the original strain. Thus the enthusiasm with which newspapers greeted the announcements by Dr. Maher are hardly justified by the value of the observations.

Tuberculosis and asthma are both conditions of great seriousness in which the evaluation of new remedies has always been difficult. Certainly a scientific physician is not justified in marketing directly to patients a preparation of uncertain standing, without even any indication from the physician of the patient as to the nature of the disease or the willingness of the physician to have the remedy administered.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Health Insurance Corporate Practice of Medicine— The insurance commissioner of California refused to permit the Pacific Employers Insurance Company to write 'A Medical Service Policy,' by which it proposed to pay not exceeding a specified amount per annum, for necessary medical surgical dental and hospital treatment in event an assured became sick or injured. Under the terms of the proposed policy however, all services were to be rendered by physicians, dentists and hospitals designated by the insurance company. The company instituted mandamus proceedings to compel the commissioner to approve the policy and the trial court directed a writ of mandate to issue. The commissioner then appealed to the district court of appeal, first district, division 2, California.

Neither a corporation said the district court of appeal nor any other unlicensed person or entity may engage, directly or indirectly, in the practice of law, medicine or dentistry. These professions are not open to commercial exploitation. It is against public policy to permit a "middleman" to interfere for profit, in establishing the professional relationships between the members of the professions and the members of the public. Taking the policy by its four corners said the court, and considering all of its provisions the conclusion is inescapable that it is basically and primarily an agreement by the insurance company, in consideration of the premium paid by the assured, to furnish the designated professional services through its appointed staff consisting of its medical director, its designated physicians and its designated specialists. It necessarily follows that issuance of such a policy would result in the insurance company's engaging in the unlawful practice of at least two of the professions, medicine and dentistry. The policy does not constitute a contract of indemnity between the insurer and the assured. It is more than a mere contract of indemnity. The company's own designation of the policy as a 'Medical Service Policy' continued the court more nearly describes the true nature of the agreement. Essentially, it is an agreement by the company to furnish medical services and other professional services through its own appointed staff of professional men rather than an agreement to indemnify the assured against indebtedness incurred for

services rendered by professional men of his own choosing. An examination of the various provisions of the policy, in the opinion of the court, fully sustained these conclusions. Throughout the 'Medical Service Policy' it is specified that the assured is entitled to various professional services, including medical and dental services under the terms and conditions set forth. One of the main headings of the policy reads 'Physicians and Surgeons, Hospital and Other Services Provided'. It is provided that the company will appoint a medical director, designated physicians and designated specialists "to render services in accordance with the provisions of the policy, and that 'The Insured is entitled to the Medical Service herein specified only when under the exclusive care and supervision of the Medical Director and/or designated physician and/or designated specialist. It is provided that if 'The Insured places himself under the care of any person' other than those appointed by the company, the rights of all further benefits under this policy shall forthwith terminate. These and other provisions of the policy convinced the court that the agreement was one by the company to furnish all the services mentioned through its own appointees.

It is a matter of common knowledge, said the court, that the general subject of health insurance has provoked much discussion in recent years. The court, however, felt disinclined to discuss this question, pointing out that if the established rules are to be changed or modified such change or modification must be made by the legislature rather than the courts.

The judgment of the trial court directing the insurance commissioner to approve the policy, was therefore reversed.—*Pacific Employers Insurance Company v. Carpenter (Calif.)* 52 P (2d) 692.

Compensation of Physicians Liability of Employer for Medical Services Rendered Employee—The manager of a branch store operated by the defendant corporation became seriously ill. He was without funds to obtain medical aid and the vice-president and general manager of the corporation requested Dr. Solomon Cameron to render the necessary treatment and assured him that the corporation would pay the bill. When the physician's statement was rendered however, the corporation denied liability and the physician brought suit. The judgment of the circuit court for the physician was affirmed by the St. Louis court of appeals and the corporation sought a reversal of that judgment in the Supreme Court of Missouri.

The corporation contended that its vice-president and general manager had no authority to obligate it to pay for the services rendered by the physician. The Supreme Court however, disagreed with this contention, and in holding that the vice-president and general manager had implied authority to act, expressed itself in agreement with the reasoning of the court of appeals, as follows:

We think the circumstances shown in the instant case afford ample grounds for presuming that Dorland as general manager of defendant, had authority to charge defendant with the employment of a physician to treat the manager of its St. Louis branch who was suddenly stricken and became desperately ill among strangers without adequate funds for the employment of necessary medical attention. Callahan [the manager of the St. Louis branch] held a responsible position of no little importance in the conduct and operation of defendant's business. Presumably he was specially trained for this position and was possessed of a knowledge of defendant's business in St. Louis not possessed by any other employee. So that defendant had a direct pecuniary interest in his speedy recovery and his early return to his work.

The Supreme Court, therefore, in effect, affirmed the judgment for the physician.—*State ex rel. Electric Household Stores, Inc. v. Hostetter (Mo.)*, 89 S. W. 2d 28.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Typhoid Carriers—Anderson and his associates calculated the typhoid morbidity in Massachusetts as a constant function of the death rate. It has been assumed that throughout the period under study (1875 to 1934) typhoid has consistently had a 10 per cent case fatality rate, so that the number of cases in any year has been ten times the number of deaths. That such an assumption is justified is shown by the unchanged case fatality rates in the larger hospitals coupled with the commonly accepted fact that aside from the dietary regimen, there has been no noteworthy advance in typhoid therapy for several generations. The use of death figures has eliminated any error due to variations in adequacy of case reporting, the death returns in Massachusetts having been reasonably complete throughout the period in question. Using this method for calculating morbidity it can then be assumed that the number of survivors from typhoid in any year was nine times the number of reported deaths. It was further assumed that 2 per cent of those who recovered from typhoid continued as carriers the duration of their lives. Consequently the number of carriers produced in any single year has been calculated as 2 per cent of the survivors in that year. It is thus possible to estimate theoretically the number of carriers produced in any period of time. An approximate figure of the number of carriers in a given population at a given time is obtained by determining the average age of typhoid patients over a period of years and knowing the average expectation of life at any age and the carrier production rate. From this the authors

conclude that the number of cases of residual (carrier-borne) typhoid (exclusive of localized outbreaks) that occur in any community in any given year is not a constant function of the number of carriers in that community but is rather a function of the carriers produced in the preceding period of approximately five years. That such a deduction is correct is illustrated by a logarithmic scale showing the decline in typhoid mortality during the last sixty years. The hypothesis suggested—that the current incidence of typhoid is a function not of the total number of carriers but rather of those recently produced—means that carriers are not all of equal importance as sources of infection and that on a community basis carriers produce fewer and fewer cases as years elapse. A carrier if undiscovered will in a period of years either infect or immunize the normal immediate environment, and subsequent infections are conditioned by the introduction of susceptible new material into the carriers' environment or sphere of influence. This is then the apparent explanation for the shift in the ratio between the number of cases in any year and the number of carriers produced in the preceding periods of years. This offers a reasonable explanation for the fact that the number of cases in any year was not a constant function of the number of carriers present in the community but rather of the number of carriers produced during the preceding period of five to ten years.

Chronic Pneumonia and Nutritional Disturbances in Infants—Greenwald and his associates call attention to the fact that there occurs in infants a chronic, nontuberculous type of pulmonary infiltration which is accompanied by nutritional disturbances and emphasize the importance and necessity of routine roentgenologic or roentgenoscopic examinations of malnourished infants whose nutritional requirements are adequately fulfilled, both quantitatively and qualitatively. During the last seven years they have observed in private practice nine infants from 3 weeks to 17 months of age who had marked anorexia and did not gain in weight yet every infant had a chronic nontuberculous pulmonary lesion. These children were observed for from three months to seven years. Roentgenologic studies showed involvement of the right upper lobe in every instance; in some infants the lower lobes and the left side also were involved. Physical signs were not always present and, when present in some of the infants there were few signs or symptoms referable to the respiratory tract. Roentgenologic changes and clinical signs and symptoms were present for periods varying from a few months to several years. The course was benign in every instance; no deaths occurred. The etiology is

obscure Whether the infiltration in the lungs in some of these children was the result of aspiration of fatty or oily substances producing lipid pneumonia, it is impossible to say. Lipoid pneumonia is sometimes the cause of chronic nontuberculous lung infiltrations, but unfortunately there is no known clinical method of determining the presence of fat in the lungs. Repeated sputum examinations for the presence of fat were consistently negative in Goodwin's patients. Lung puncture might be tried, but whether consistent and sufficient information could be obtained to justify its use is questionable.

Direct Venography in Obstructive Lesions—In using direct venography in thirty-seven cases, Barker and Camp employed diodrast as their injection medium. Injection was made in the long saphenous vein or one of its tributaries in the lower part of the leg when visualization of the upper long saphenous, upper femoral or iliac veins was desired, in a superficial vein of the outer side of the foot or posterior part of the calf when visualization of the short saphenous, popliteal or lower femoral veins was desired and in the median basilic vein at the elbow when visualization of the axillary and subclavian veins was desired. A tourniquet or manual pressure was used to distend the vein and direct venipuncture was made with a number 21 needle attached to a Luer syringe. The tourniquet was removed before injection was begun. In veins of the lower extremity, 20 cc of diodrast was injected and 10 cc in veins of the upper extremity. Injection was made steadily and rapidly, from fifteen to eighteen seconds being taken for 20 cc. The roentgenogram was made just as injection was completed. For visualization of the saphenous, femoral and iliac veins 90 kilovolts (peak), 60 milliamperes, 30 inch tube film distance and one and a half seconds for exposure were used. The tube was at an angle of 5 degrees cephalad. For examination of the axillary and subclavian veins the following factors were used: 70 kilovolts (peak), 60 milliamperes, 40 inch tube-film distance and one second exposure. It was found that, even with rapid changing of films, diodrast passed out of the veins too rapidly to secure visualization in more than one film. Of the thirty-seven cases successful venograms were made in nineteen cases of veins in the lower extremity, seventeen of veins in the upper extremity and one of the external jugular vein. Pain was not felt in the veins during or following injection, nor did thrombosis occur after injection. Nausea developed in three cases and two of these patients vomited within two minutes after injection was completed, several others complained of "light-headedness." These reactions were transient and probably due to the rapidity of injection. Nausea and vomiting occurred only in cases in which 20 cc of diodrast was injected and in cases of extensive venous obstruction in which there was marked slowing of the venous blood flow. Mild urticaria developed in a patient within fifteen minutes after injection, the patient later said that this had occurred previously when she had taken iodides. Normal venograms can be described as follows. In the upper extremity the median basilic vein after its injection and the axillary and subclavian veins are clearly visualized to a point at which the subclavian passes the lower margin of the clavicle and in the lower extremity, the long saphenous vein after its injection is well visualized to its juncture with the femoral vein and from this point the femoral and iliac veins are more faintly seen to the beginning of the inferior vena cava. Direct venography aids in evaluation of disturbances in the rate of the venous flow of blood and in localizing and determining the extent of an obstructive lesion, and is of diagnostic aid in obscure cases. Contraindications to its use are idiosyncrasy to iodides and recent (within two weeks) acute thrombophlebitis.

Tuberculosis of Tuberosity of Ischium—Kaplan adds a case of tuberculosis of the tuberosity of the ischium to the seven reported in the literature during the last thirty-five years. Tuberculosis of the ischium in the young is relatively easy to cure. In an adult visceral complications are less often present. Early and radical treatment will produce a rapid and early cure. When simple curettage fails to produce cicatrization, it may be necessary to do a partial resection subperiosteally. Rest in bed and immobilization are necessary to complete the cure.

Virus of Pemphigus and Dermatitis Herpetiformis—Urbach and Wolfram obtained material from thirty-four patients with pemphigus and dermatitis herpetiformis in an attempt to prove the identity of these dermatoses with the group of diseases caused by an invisible virus. Animals (288) inoculated subcutaneously with blister fluid exhibited signs of the disease in 91.8 per cent of cases of pemphigus, 100 per cent of cases of localized pemphigus and 70 per cent of cases of dermatitis herpetiformis. The histologic changes registered in the brain substance of the experimentally infected rabbits were always those of meningo-encephalomyelitis. Animals inoculated with virus from patients with pemphigus showed the same symptoms as those into which material from patients with dermatitis herpetiformis had been introduced. Just as the course of dermatitis herpetiformis is milder in human beings, so in animals it is characterized by lesser morbidity and mortality. The symptoms point unreservedly to one and the same pathogenic agent as responsible for both pemphigus and dermatitis herpetiformis. The symptoms and histologic changes observed in passage animals correspond exactly to those occurring in animals infected directly with human virus. Since microscopic and cultural studies gave invariably negative results, it must be assumed that we are dealing with an invisible virus, necessarily filterable, because the transfer of the infection from the human being to animals and its further passage through animals was successful with filtered material. The involvement of the central nervous system was marked in all animals infected with material obtained from patients with pemphigus in the florid stage. The picture composed by the symptoms and the histologic changes in the central nervous system closely resembles that produced in animals by the virus of herpes. Attempts to secure crossed immunity between pemphigus and herpes failed, while animals which recovered from an attack of pemphigus usually displayed an immunity to reinfection with pemphigus. The supposition that pemphigus is caused by a virus is further strengthened by the results of inoculations of animals with material obtained from the two patients at necropsy. Passage through animals was successful in both cases; the material used consisted of filtrates of normal and diseased skin, spleen and lymph nodes. By serologic tests they were able to demonstrate that the disease manifested by their animals was the same as pemphigus in human beings.

Pyoderma Gangraenosum—Cohen feels that in his case of pyoderma gangraenosum the marked ulcerations of the skin and the intestine, the smooth, atrophic tongue, the hypochromic anemia, the long intermittent course and the lack of any evidence of contagiousness suggest a deficiency disorder. He ascribes the fact that the patient was not cured by vitamin therapy to the destruction of the absorptive mechanism in her intestinal tract and to the complexity of the involved vitamins. He believes that cases of pyoderma gangraenosum are more common than the literature would lead one to believe, that particular attention should be given to the skin of any patient suffering from long continued diarrhea and that it is essential that a high vitamin diet, liver extract, iron and calcium be given early in the course of such a condition. The final word on the etiology of pyoderma gangraenosum and ulcerative colitis remains for the future to supply, but it is his opinion

that this condition is not of an infectious nature but is due to the lack of some protective substance or vitamin in the skin and intestinal tract

Fatality Following Bismuth Arspenamine Sulfonate Therapy—Swartz and his associates cite a fatal case of fat embolism following the use of bismuth arspenamine sulfonate in antisyphilitic therapy. At necropsy the fatty changes in the liver were not pronounced, there being only periportal lymphocytic infiltration and relatively insignificant infiltration of the liver cells of the central portion of the lobule. It was difficult to believe that these changes brought about the abrupt and severe grade of jaundice which developed. Although stones were found in the gallbladder, there was no intrinsic or extrinsic obstruction of the biliary tract. The myocardial scar seemed unlikely to account for the patient's death. The fat embolism of the lungs, on the other hand, was so widespread that it alone may be considered as adequate to explain the fatal outcome. By effectively plugging the pulmonary capillaries, the fat emboli produced what Warthin referred to as the respiratory symptom and pathologic complex of fat embolism. With general reference to the category of toxic causes of fat embolism and with special reference to the present case, there are two recently reported fatalities from fat embolism following arsenic therapy for syphilis reported by Burns and Bromberg and Brittingham and Plunizy. It has been demonstrated that it is the arspenamine radical common to bismuth arspenamine sulfonate and to the other arsenic compounds which is responsible for the untoward reactions occurring during treatment. The authors therefore believe that the present case is of the same type as those reported by the foregoing investigators.

Study of Lower Lobe of Lung—Levitin and Brunn state that the lower lobes of the right and left lungs are divided into two distinct parts: (1) a small triangular superior division and (2) a larger inferior division. This anatomic fact has been insufficiently emphasized in the past. Each portion of the lobe has its own bronchial distribution. Embryologically, each develops from a separate anlage. A fissure separating the two parts may be observed in the developed lung. The pleural reflection in the fissure may be observed in the roentgenogram and has often been misinterpreted as a pleural adhesion. This definite anatomic structure accounts for numerous limited disease processes the localization of which has previously not been understood. In the roentgenogram the involved superior division appears to lie high in the chest or low behind the diaphragm, depending on the position of the diaphragm when the roentgenogram is made. Failure to recognize the importance of the position of the diaphragm has often led to misinterpretations. When the process appears high in the roentgenogram it is often diagnosed as central pneumonia. When it appears low, it may be mistaken for encapsulated fluid.

Jaundice in Syphilis—Sager declares that slight transient jaundice may be encountered in cases of syphilitic cirrhosis but that neither this condition nor gumma of the liver gives the familiar picture of benign or fatal jaundice. In his records of thirty-one cases there were twelve cases of gumma of the

liver, syphilitic cirrhosis or hepar lobatum, in only one instance was jaundice present, and in that case it was faint and transient. A careful search of the records of cases of tertiary syphilis of the liver with postmortem observations reported by various observers, both before and after the introduction of arspenamine, failed to reveal in a single case a condition that will fit into the picture of acute yellow atrophy. Nor are the clinical pictures of the two diseases alike. On the other hand, lesions in cases of fatal paratherapeutic icterus are always those of acute or subacute yellow atrophy or coarse nodular cirrhosis; the familiar lesions of hepatic syphilis are uniformly absent and spirochetes are never found as pointed out by Ravaut and Fischer. Even if gumma or syphilitic cirrhosis should be found in association with acute yellow atrophy, the etiologic relation of the two would not thereby be proved. But the author is not aware of any case in which this association was present.

Caffeine and Dextrose for Reducing Cerebrospinal Fluid Pressure—Blau compared the effects on the cerebrospinal fluid pressure of the intravenous administration of hypertonic dextrose (50 per cent) and sodium chloride (15 per cent) solution and a solution of caffeine with sodium benzoate (5 grains or 0.3 Gm.) in fifty-one observations on normal persons and on patients with increased intracranial pressure. The injection of dextrose solutions was effective in reducing the cerebrospinal fluid pressure in but relatively few cases. In a few cases the injection of a dextrose solution caused an immediate prolonged rise in the pressure. The effect of caffeine was greater and was consistent but with both the latter and the dextrose the results were transient. The injection of hypertonic sodium chloride solution, however, resulted uniformly in a definite and more persistent reduction in the cerebrospinal fluid pressure. Hypertonic solutions of sodium chloride should replace the solutions of dextrose in clinical administration for the reduction of intracranial pressure.

Arrhenoblastoma—McLester cites a case of an ovarian tumor that falls into the group of twenty-nine previously reported cases of arrhenomastoma. The secondary sexual characteristics of the woman, originally feminine, changed materially in the course of three years to definitely masculine. After removal of the tumor the feminine characteristics returned to a partial degree, and after one year there has been no recurrence of the tumor or return of the male characteristics. The mass was ovarian in origin. The return of feminine characteristics and particularly the continued normal menstruation after the operation are indicative of a normal function of the remaining gonadal tissue. The tumor consisted, probably, of testicular tissue. There was cord formation but no attempt at the construction of tubules or acini, nor was there any spermatogenesis. The chief cells were of two types. One was suggestive of endocrine structures in general. The second type of cell was fusiform, suggestive of embryonic fibrous tissue, with some evidence of change into the former type. Columnar, mucus-producing epithelium with typical goblet cells was found in the walls of a cyst of the tumor. The tissue was entirely quiescent and was taking no part in the active proliferation shown by the actual tumor cells. This structure, since it is foreign to ovary or testis, puts the tumor into the group of teratomas. The tumor may prove to be benign. Nothing was noted to indicate the cell type from which the tumor arose. It is not unlikely that a group of fetal cells in the ovary, growing in response to an unknown stimulus, might well have been the source of the patient's tumor. Clinically the growth was identical with the arrhenoblastomas; pathologically it was highly suggestive at least of the more undifferentiated types as they have been described. This suggests that the previously reported arrhenoblastomas may have been a special type of teratoma.

Roentgen Interpretation of the Painful Shoulder—Unfug states that painful shoulders may be due to cervical rib arthritis of the shoulder, arthritis of the cervical spine calcified cervical glands acromioclavicular separation and arthritis of the acromioclavicular articulation. Cervical ribs may vary in size from an elongated transverse process of one of the lower cervical vertebrae to a separate rib several inches in length. Only 5 per cent of cervical ribs give a brachial plexus effect. The shoulder pain from arthritis of the cervical spine is difficult to explain. Some of it however, is due to involvement of the brachial plexus. The bony exostoses with or without narrowing of the joint space and bone destruction visualized on the roentgenogram are well known. In shoulder pain due to calcified cervical glands the pain is believed to be due to a mechanical or inflammatory irritation of the brachial plexus. Acromioclavicular separation is not uncommon. Clinically, one is often misled by a false crepitus or grating sensation which may be encountered in almost any normal acromioclavicular articulation. Roentgenographically, one can be misled if only the usual view of the shoulder is taken. Frequently it is necessary to make roentgenograms with the arm in two positions, abduction and adduction and it has been found that plates made with the patient standing will frequently reveal a separation when all other methods fail. Arthritis of the acromioclavicular articulation is evidenced on the roentgenogram by mixed hypertrophic and atrophic changes and by a narrowing of the joint space. Its chief importance from the roentgen point of view, lies in the fact that a true arthritis of the joint must be differentiated from simple hypertrophic excrescences of the acromion, which are occasionally secondary to an old injury of the supraspinatus tendon. Whenever only hypertrophic changes are visualized about this joint a careful study should be made to exclude previous supraspinatus tendon injury. The roentgen observations most frequently encountered are (1) calcified deposits in the supraspinatus tendon, near its insertion, (2) excrescences on or roughening of the greater tuberosity of the humerus, (3) area of increased density in the greater tuberosity at the insertion of the supraspinatus tendon (eburnation), (4) roughening of the outer edge of the greater tuberosity below the insertion of the supraspinatus tendon (bursal osteitis), (5) areas of bone absorption beneath the greater tuberosity (cavities), (6) recession of tuberosity—disuse (7) trabecular atrophy in the greater tuberosity beneath the base of the bursa, and (8) hypertrophic changes at the edge of the acromion process.

Treatment of Furunculosis—Prey and Foster have found an ideal method of treating furunculosis by combining the local application of contractile collodion to the furuncle and the intravenous injection of colloidal animal charcoal. The charcoal preparation that they have used comes in 3 and 5 cc ampules. In the milder infections 3 cc. has been ample. The injection may be repeated in forty-eight hours, with perfect safety, if deemed necessary. The local application of contractile collodion is carried out as suggested by Robbins. This form of local therapy relieves the pain instantly, protects the surrounding skin, permits the application of a small dry dressing and is not incompatible with other methods of treatment. The collodion must be of the contractile quality not the flexible, and is applied by means of a saturated swab. From ten to twenty strokes are made around and on the boil a small opening being left

at the center, where the boil seems to be pointing. The collodion should be applied thickly and should extend well beyond the edge of the furuncle. As the collodion dries, the pain is relieved within thirty seconds and wrinkles will appear, extending on to the surrounding skin, demonstrating its contractility.

Migraine and Ovarian Deficiency—Glass made quantitative hormone assays before and after endocrine therapy in ten migrainous women. Quantitative assays of estrogenic substance and of the follicle stimulating factor in the blood and urine were made during one menstrual cycle before, and repeated once or twice after, endocrine therapy. The symptomatic management before endocrine therapy was instituted gave little or no permanent relief to the majority of these women. The nature of the menstrual disorders varied but usually some degree of menorrhagia oligomenorrhea or dysmenorrhea was present. Headaches occurred most frequently in relation to the actual menstrual flow, but most often in the premenstrual period. Sterility appeared prominently in the histories of six cases. Eight women responded readily to estrogenic therapy and by hormone assays after treatment, it was determined that the follicle stimulating factor output was actually being suppressed. It may be concluded that its excess can be controlled by adequate estrogenization in the human being as well as the animal. Not only was there striking relief and control of the headaches but menstrual function was more or less normalized and general well being remarkably improved. This definite association of ovarian dysfunction with migraine may promote the investigation of many migrainous subjects. Relief has been maintained for periods varying from six to thirty-six months. However, relapses do frequently follow cessation of treatment and omission of treatment in three cases was followed by a return of the original hormone imbalance as well as the migrainous state. Estrogenic substance was used in doses (from 8,000 to 32,000 international units) adequately potent for the suppression of the gonad stimulating factor called 'prolan'. Relapse or failure to control the migraine seemed to be directly due to inadequate or infrequent estrogenization.

Iodine Tolerance Test of Thyroid Function—Watson determined the relative rate of the disappearance from the blood of intravenously injected iodine in thirty cases by the following method. With the patient in the fasting state in the morning,

an amount of compound solution of iodine containing 250 micrograms of iodine per kilogram of body weight, after being diluted with 15 cc of 0.85 per cent solution of sodium chloride, is injected intravenously. Samples of venous blood of about 12 cc each are obtained immediately before the injection and five minutes, two, four and six hours afterward. These samples are received in tubes containing a small amount of potassium oxalate. Food is withheld from the patient during the test period. The concentration of iodine in each sample of whole blood is estimated by means of a method described by Perkin. In this procedure 10 cc of blood is placed in a nickel crucible together with 2 Gm of potassium carbonate and combusted on a hot plate and in a muffle furnace for four and one half hours. The charred mass is extracted with alcohol and filtered and the filtrate is evaporated to dryness. The residue is dissolved in water and, when the solution is made slightly acid with sulfuric acid and a drop of freshly prepared bromine solution is added, the iodine is oxidized to iodate. The addition of potassium iodide frees the iodine, which is estimated by titration with 0.001 normal sodium thiosulfate solution with starch serving as an indicator. The iodine content of the blood specimen secured five minutes after the injection of the iodine solution minus that of the preliminary control sample is regarded as representing the maximal increment caused by the injected iodine and is consequently recorded as 100 per cent. With this value as a basis, the observations for the other samples are expressed accordingly. While the results so obtained represent the relative rather than the absolute iodine concentrations, they do provide an indication of the rate of disappearance from the circulating blood of the injected iodine in a specified time. In thirteen of sixteen individuals with clinically normal thyroids, from 9 to 23 per cent of the injected iodine remained in the blood stream six hours after its injection. In six of ten patients with thyrotoxicosis, none of the injected iodine remained in the blood stream after six hours and in none of these cases was more than 5 per cent of the injected iodine found to be present at this time. In four cases of hypothyroidism the average quantity of iodine in the blood six hours after its injection was greater than normal. The iodine tolerance test may be of diagnostic importance in cases of doubtful thyroid disease.

Purification of Diphtheria Toxin.—Eaton endeavored to isolate diphtheria toxin in a pure state. The purification procedure is as follows. 1 To the crude toxic filtrate 18 cc. of 20 per cent calcium chloride solution per liter of toxin is added allowed to stand for fifteen minutes and filtered through folded paper. 2 To the filtrate 233 Gm of ammonium sulfate per liter is added, kept at p_H 7 by the addition of a few cubic centimeters of tenth normal sodium hydroxide allowed to stand one hour in the refrigerator and the precipitate filtered off on

folded paper. 3 To the cooled filtrate 70 cc. of 10 per cent aluminum ammonium sulfate per liter is added and well shaken. The p_H should be about 6. This is stoppered and kept in the refrigerator overnight. The heavy precipitate is filtered off in a Buchner funnel. 4 The precipitate is ground with water in a mortar and suspended in a volume of water one third the volume of the original crude toxin, kept in the refrigerator for several hours and filtered on a Buchner funnel. 5 The precipitate is dissolved in a 2 to 4 per cent solution of sodium citrate using one twentieth the volume of the crude toxin and the Lf value is determined. (An Lf unit is the volume of toxin flocculating with one unit of antitoxin.) 6 The citrate solution of the alum-precipitated toxin is diluted so that it contains from 100 to 120 Lf units per cubic centimeter. The citrate concentration is adjusted to optimum for cadmium precipitation by adding a 5 per cent solution of cadmium chloride until a moderately heavy precipitate forms and the p_H is about 6. From one-half to one volume of cadmium chloride is required, depending on the citrate concentration, kept in the refrigerator for two hours and the cadmium toxin precipitate centrifuged down. 7 The precipitate is washed with a volume of water equal to the toxin solution before cadmium chloride precipitation and then filtered on a Buchner funnel. The precipitate is treated with from one fourth to one half its volume of a 2 per cent solution of sodium phosphate U S P or a 1 per cent solution of sodium bicarbonate and allowed to stand for several hours or overnight in the refrigerator with occasional mixing. 8 The insoluble cadmium phosphate or carbonate is centrifuged down at high speed and the resultant red or red brown supernatant contains the concentrated and purified toxin. Purified toxins containing 0.0005 mg of nitrogen per Lf unit and 0.00002 mg of nitrogen per minimal lethal dose have been obtained.

Observations on Nature of Diphtheria Toxin.—The additional experiments of Eaton with the progressive purification of diphtheria toxin show that the ratio of nitrogen to Lf units in the toxin preparations appears to approach a constant value near 0.0005 mg of nitrogen per Lf unit. None of the several purification processes so far used have yielded toxins with a lower N/Lf ratio. The highly purified toxins consist mainly of a protein which is not easily precipitated with acid at any p_H and contains no cysteine sulfur and very little or no tryptophan. Traces of proteoses from the culture medium, and of other proteins probably derived from the bacterial cells, are also present. The chemical, immunologic and physiologic properties of diphtheria toxin observed in the course of this work indicate that it is a single protein-like substance.

Poison Ivy Hypersensitiveness—Simon investigated the influence that the state of health and nutrition of guinea pigs had on the development of hypersensitivity to poison ivy. He found that a dietary deficiency in vitamin C inhibited the development of hypersensitiveness to poison ivy. A well developed hypersensitiveness was demonstrated seven days after the first application of the extract. Injection of the extract intramuscularly, intraperitoneally and intravenously did not result in hypersensitiveness or did so to only a slight degree whereas application to the surface of the skin resulted in a definite hypersensitiveness. Excision of the area of skin to which a sensitizing application had been made was ineffective in preventing the development of hypersensitiveness if excised from eighteen to twenty-four hours or longer after application. Excision of the site before this time prevented the development of sensitization. The method of spread could not be determined. Histologic study of the lesions revealed evidence of an acute inflammatory reaction in both the epidermis and the papillary layer of the corium, with considerable necrosis of epidermal cells. This reaction was observed in both a sensitized and a nonsensitized guinea-pig but was definitely more marked in the former. Attempts to sensitize the rat rabbit and cat to poison ivy were unsuccessful.

Respiratory Failure in Acute Epidemic Poliomyelitis—Brahdly and Lenarsky found the Drinker respirator useful only in patients with paralysis of the respiratory muscles due to lesions in the spinal cord. The patients with injury of the respiratory center who were treated in the respirator all died. Such patients, as well as those with obstruction of the upper air passages due to inability to swallow saliva, mucus or vomitus, do better when treated by other methods. Patients with lesions of the spinal cord that cause paralysis of the diaphragm or thoracic muscles and who have definite signs of respiratory difficulty should receive treatment in a respirator. On the other hand, patients with slight evidence of respiratory embarrassment without dyspnea or cyanosis should not be placed in a respirator. When a patient has any involvement of the

respiratory muscles or evidence of an ascending paralysis he should be near a respirator, as there is no way of telling whether the condition will become worse. Follow-up data were obtained in the twenty-seven of the sixty-three patients who were discharged from the hospital. Some recovered use of their paralyzed muscles and are normally active children, others are handicapped but are able to get about and several are bedridden. After leaving the hospital twelve patients died from some pulmonary condition but in only two of these were roentgenograms taken. These were the only two fatal cases in which a diagnosis of massive atelectasis was made. Clinically atelectasis is frequently mistaken for pneumonia and in some of the nine patients in whom a diagnosis of pneumonia or pulmonary edema was made the history strongly suggested the possibility of atelectasis. Massive atelectasis developed but was not fatal in five patients. Thus massive atelectasis developed in seven of the twenty-seven patients who survived their original respiratory paralysis.

Edema and Chronic Dietary Insufficiency—Over a period of nine years Dodd and Minot collected reports of forty-one cases of edema in which a thorough study of the patient revealed no evidence of cardiac or renal involvement. Some times the edema was confined to the feet and legs but there were several instances of generalized anasarca. The condition was observed in children from 4 months to 9 years of age. Five children of the group had no demonstrable disease other than generalized edema, nine either had or were convalescent from bacillary dysentery, ten had diarrhea with stools not typical of dysentery, three had pneumonia, two were diagnosed as having celiac disease and three showed evidence of scurvy. There was one case each in which edema complicated pellagra, typhoid, tuberculous enteritis, diabetes and a common cold. Four children had histories of repeated infections. The previous diet was known to be good in three cases. In most of the other instances the diet offered was grossly deficient or there had been a long period when the appetite was poor. Breast feeding had been continued long after the supply of milk was sufficient and supplementary foods had not been offered. The older children ate only potatoes, corn bread, turnip greens and beans. In twenty-six of the forty-one cases, various fractions of serum protein were made. The majority were children who were poorly developed and undernourished but not critically ill in whom a mild acute or chronic diarrhea apparently brought out a latent edema. The levels of hemoglobin observed give further evidence of their poor nutritional state. The levels of total protein and serum albumin were lower than any generally accepted range of normals. The most marked reduction is in the albumin fraction. Occasionally the globulin is reduced but in a majority of instances is normal or increased above the average. In most instances treatment of the primary disease together with a high protein diet and transfusions of blood when necessary, brought about a prompt reduction of edema followed by a gain in real weight and recovery. Determinations of serum proteins during the recovery period showed a gradual increase to normal levels. In cases in which the edema was associated with the nonspecific type of diarrhea the serum proteins were raised to a more normal level, the edema disappeared and the diarrhea subsided. This observation throws some doubt on which is primary and which secondary when nonspecific diarrhea and nutritional edema occur together in infants and children.

Occurrence of Moderately Reduced Serum Albumin—Dodd and Minot noticed that many children who entered the hospital with acute diseases tended to develop edema very easily when moderate amounts of parenteral fluids were given. It seemed possible that many of the children might have milder degrees of the same nutritional deficiency which had led to outspoken edema, and in this event the nutritional disturbance would be analogous to subclinical vitamin deficiency. Therefore the serum protein levels of 500 children who came to the clinic were determined. For comparison with these results a smaller group of well children of various ages, who were known to be on adequate diets were similarly studied. The results of the studies confirm the observations of others that the serum proteins of infants are low and increase gradually to approximately the adult level at 2 years of age. The general level of serum albumin of the authors' clinic group, even in

the absence of acute or chronic illness, is somewhat below that of the normal group. The serum albumin in children with acute or chronic infection rarely reaches the normal average except in the presence of dehydration. The work indicates that a chronic low grade deficiency in serum proteins is common among the poorer children in the community. The diet, which is low in total calories and in protein, is probably the cause of the deficiency. Such children are predisposed toward the development of edema, especially in the presence of infection.

*Two Unusual Transfusion Reactions P A Young Boston.—p 879

Unusual Transfusion Reactions—Young states that, of his two transfusion accidents, one happened as the result of using a dangerous technic of matching blood. This faulty technic consists of placing a drop of the patient's serum on a glass slide, adding a drop of a saline suspension of the donor's cells and dropping a cover slip on the mixture. If the two drops are large there is enough space between the slide and the cover slip for the red blood cells to move about freely. If small drops are used, the liquid spreads out in a thin film and the red blood cells are fixed between the two glass surfaces. In this particular case the "cross matching" was observed for half an hour and checked by another intern. Immediately after the transfusion accident the matching was repeated by the same technic, with the original serum and suspension of cells. Again there was no sign of agglutination in an hour, but with the hanging drop technic agglutination occurred within five minutes. The patient's blood was found to be a group IV (Moss) and the donor's a group II. In the other instance both the patient and the selected donor had been grouped and doubly cross matched, i. e., the patient's cells in the donor's serum and the donor's cells in the patient's serum. Both the grouping and the cross matching were done by the hanging drop method. The patient and the donor were in group II (Moss) and no agglutination occurred in either of the cross match' tests within half an hour. However, immediately after the transfusion accident all the tests were carefully repeated, with the finding that the donor's cells began to hemolyze in the patient's serum after forty minutes and were completely hemolyzed

within sixty minutes. In the first case citrated blood was pumped into the vein under pressure, about five minutes being taken to introduce 300 cc. The symptoms commenced in less than a minute after the transfusion was completed, or in about six minutes after the start. In the second case whole blood by the new B-D grooved syringe method was introduced at the rate of about 15 cc per minute. Symptoms developed after 90 cc of blood had been given—about six minutes after the start. Transfusion was repeated in both cases a few days after the accidents and no symptoms of any type were observed.

Peptic Ulcer in Childhood—Williams reports the occurrence of peptic ulcer in a boy, 5 years of age, who had always been in average good health and whose past history was negative except for minor disorders. He was seen in January 1932 with the complaint of recurrent pain in the abdomen. The onset of the disturbance dated back several weeks and, although the diet had been carefully restricted, there had been no improvement. At certain periods of the day he showed definite evidence of considerable distress in the abdomen. The pain awakened him at night, usually in the early hours of the morning. The physical examination was negative and it was impossible objectively to discover the reason for his apparent distress. There had been no elevation of temperature at any time. There was no abdominal rigidity, no tenderness to pressure and no distention. There had been no vomiting and no intestinal disturbance. Occult blood was not found in the stools. The absence of physical signs and the character of the pain suggested the possibility of ulcer. This diagnosis was verified by roentgen examination, which revealed a niche in the cap of the duodenum. The child was placed on a modified Sippy diet consisting of milk and bland foods given at frequent intervals, with the addition of alkalis. Improvement was noted almost at once and complete healing was accomplished after its continuance for several weeks.

Dermatitis Due to Heat Decomposition of Dyes—Schwartz and Hocker investigated the cause of a dermatitis occasionally contracted by certain susceptible telephone cable splicers. The chief method used in the investigation was careful observance of rash-susceptible workmen occupationally engaged in planned cable-splicing tests. Patch tests and chemical studies were used as supplemental methods of investigation. Paper pulp cable conductor insulation, suspected as a possible cause of the rash, was not found to be the cause of the dermatitis. Splicing oil, a refined white mineral oil, was not a primary cause of the dermatitis. Mixtures of this oil and paraffin heated to nearly 400 F are used to "boil out" (dry and impreg-

nate) cables while opened for splicing. The dermatitis was found to be produced by some irritant evolved during boiling-out operations. The rash occurred only while cables were being spliced in which the conductor insulation was colored with green and blue dyes. A red dye also normally used did not cause the dermatitis. Contact with the dyes themselves was shown not to be the chief cause of the rash, although a substantial quantity of the green dye applied in a patch test would cause skin reactions. The rash was not produced in cable-splicing tests in which the green and blue dyes were present if liquid petrolatum containing no splicing oil was used for boiling out. Apparently the oil is necessary as a fume carrier or as an agent present on a man's skin to facilitate the action of the volatilized irritants. The volatilized irritants were not certain suspected decomposition products of the dyes. While the irritants were not identified by experiment their nature was fairly definitely surmised from chemical considerations. Splicing experiments with rash-susceptible men showed that the new dyes selected for experiments did not produce a rash even when splicing oil was present in the boiling out compound. The seven splicers who had dermatitis and who were used in these experiments also had fungous infections on various portions of their bodies. This may be of significance as to their hypersensitivity to the decomposition products of the dyes.

Inclusion Bodies in Trachoma.—From March 15, 1935 to Feb. 1, 1936, Rice observed ninety-six individuals with varying degrees of lid activity in an effort to determine whether the epithelial cell inclusion might be associated with a certain period of the disease. Forty-nine of 184 actively infected eyes or 27 per cent showed the presence of epithelial inclusions. Of fifty-one cases under two years duration, nineteen showed inclusions. Of forty-five cases with duration of the disease of two years or longer there were eight cases showing inclusions. The study seems to indicate that the epithelial cell inclusion seen frequently in this disease is much more likely to be found during the first six months of the disease than it is later. The oftener the examination can be done during the first eight weeks of the disease, the higher will be the percentage of cases showing the presence of the inclusion bodies.

Intravenous Use of Hypertonic Dextrose in Obstetrics.—Matthews and Mazzola observed a group of ten cats in which shock with low blood pressure was artificially produced by hemorrhage and ten cats in which it was produced by trauma without hemorrhage. They found that the injection of a 50 per cent solution of dextrose into cats with artificially reduced blood pressure produced a rise in blood pressure, an increase or a return to the original pulse pressure and a slowing or a return

to the original pulse rate. The first group of cats received dextrose previous to bleeding and they reacted to hemorrhage much better. The results indicate that the diminished blood pressure, the rapid pulse and the fall in pulse pressure subsequent to hemorrhage in the experimental animal can be combated. In the second group injections of the solution produced a rise in blood pressure, an increase or a return to the original pulse pressure and a slowing or a return to the original pulse rate. The results showed that the low blood pressure and the rapid pulse subsequent to trauma can be temporarily, at least, successfully combated by the intravenous injection of the 50 per cent solution of dextrose. Furthermore, if a fortifying dose is given the cat before trauma is performed, the subsequent fall in blood pressure and acceleration of the pulse are finally maintained more near the normal or above it than when no previous dextrose is given. Clinically in cases of hypotension, intravenous 50 per cent solution of dextrose with routine preoperative rest gives the patient a wider margin of safety for operation. Cases of acute hemorrhage with diminished blood pressure have shown increase in blood pressure by the intravenous injection of 100 cc of the solution. It tides these patients over until blood transfusion can be started. In primary shock or collapse it increases systolic blood pressure and greatly aids in bringing the circulation back. Preoperative dextrose makes reduction of blood pressure from hemorrhage or prolonged surgery more difficult. After operation it aids in overcoming acidosis and dehydration. By its action on the circulation physiologic solution of sodium chloride administered by hypodermoclysis is more readily absorbed. It also aids in supplying carbohydrates when the oral route is contraindicated. In shock with or without hemorrhage the dextrose solution is to be commended. Active treatment must be instituted before there is complete circulatory collapse. The patient who receives prompt treatment is the one who recovers. When blood is not available or when time is pressing, concentrated dextrose solution makes an excellent substitute. Concentrated dextrose preoperatively maintains pulse pressure, causes a slight rise in systolic blood pressure and if repeated, prevents a fall. It diminishes postoperative vomiting and has considerable value as a food in the presence of peritoneal infection. Little or no damage is done the vein by its injection, provided the intima of the vessel is not excessively traumatized.

Paget's Disease and Osteoporosis.—Moehlig shows that Paget's disease and osteoporosis may occur in the same family. Data were gathered in ten cases of osteoporosis which showed that there was a diabetic family history in 40 per cent, 60 per cent had one or more members of the family who were 72 or more inches tall and 90 per cent gave a history of heavy set individuals in the immediate family. This corresponds with the data obtained in Paget's disease. In ten cases each of Paget's disease and osteoporosis the dextrose tolerance curves showed a diabetic type of curve. All patients with Paget's disease had an elevated plasma phosphatase. The plasma phosphatase was about normal in the patients with osteoporosis. The ages of the patients with Paget's disease ranged from 34 to 60 years, average 48 years. There were six male and four female patients. In the osteoporotic group the ages ranged from 46 to 57 years, average 52 years. There were two male and eight female patients. The pathologic condition at one stage is the same in the two diseases, i. e., osteoporosis, in Paget's disease the process goes on to the hypertrophic state with hypertrophic osteoid formation. The pituitary gland may be responsible for the two diseases, since it is concerned with skeletal development and carbohydrate metabolism. Furthermore osteoporosis of the spine is present in acromegaly and the pituitary basophilia of Cushing. Hyperglycemia is frequently present in the two diseases and it is reasonable to assume that the disturbed pituitary function is related to the disturbed carbohydrate metabolism and the osteoporosis. Definite subjective improvement is noted in Paget's disease by giving a measured diet with insulin. One patient receiving this form of treatment for more than four months shows progression of the process in the skull although subjective improvement continues.

Longitudinal Overgrowth of Long Bones.—Bisgard investigated the problem whether the shortening in long bones is overcome by lengthening at the fracture site or by accelera-

tion of the rate of normal growth at the epiphyseal line. To this end he experimented on twenty-five kid goats. He summarizes the results of his investigation as follows: 1 Lengthening in excess of normal occurs in growing bones following fracture. The greatest gain in length takes place in the second month but continues at a much slower rate for at least seven months. 2 The excess length is gained at the ends of the shaft through an acceleration in the rate of osteogenesis, or, in other words, an increase in the activity of the processes responsible for normal growth. 3 Excessive growth occurs irrespective of the length of the bone or of the necessity of equalizing the length of extremities. If no shortening exists, actual overgrowth results (the fractured extremity becoming longer than the normal one). 4 Since excessive growth is localized to one extremity and usually confined to the fractured bone, it is believed that the stimulus responsible for it is likewise local. 5 Shortening alone, in the absence of a fracture, did not cause an acceleration of growth. Thus it is apparent that if there is a compensatory mechanism within the body which is capable of regulating growth in an effort to maintain equality in the length of extremities, shortening alone does not excite this mechanism. It must be conceded, therefore, that the fracture and the reparative processes supply the stimulus, and it is suggested by the results of the experiments that this stimulus is merely incidental to the prolonged abnormal status of the circulation of the part caused by the fracture and its subsequent repair. This contention is also supported by reported clinical data.

Physical Reactions to Functional Disorders—Sanders believes that, when it is realized that there is a nervous counterpart for every organic disease and that no form of physical damage exists which is not imitated and reproduced by sensations practically identical with those accompanying organic disease, it is easy to understand the enormous variety of nervous symptoms and the unlimited manifestations of nervous discomfort. Physically, the individual with a neurosis is usually underbuilt, is only fairly well nourished, has cold, moist palms, rapid pulse, anxious mien, spastic colon and exaggerated peripheral reflexes and is hypersensitive to pain. With a patient presenting such an emotional and physical background, the physician may well be cautious in condemning certain organs for removal or in prescribing drugs and diets. Too often such a patient grows worse, because what he needs is not surgery or diet or drugs but a readjustment of ideas and rest. The present day physician must realize that more than half of his work is directed to the overcoming of functional not organic, diseases. After the nervous balance has been restored and physical strength renewed, surgical procedures for chronic conditions may be safely done without fear of further damaging the nervous system. When the physical reactions of deranged organs or systems are known to be due to functional disorders from whatever cause, surgical procedures merely add insult to injury and further damage the already breaking nervous system. The only sound and abiding basis for the cure of functional disorders, on a psychic or nervous basis, is rational reeducation.

Mechanism of Immunity in Rift Valley Fever—Findlay states that, as the result of acquired active immunity, Rift Valley fever immune bodies can be demonstrated in the serum of human beings from four to five years after infection. Certain mixtures of Rift Valley fever virus and immune serum, apparently neutral when injected intraperitoneally, can be reactivated or dissociated by simple dilution with saline solution. This phenomenon is quantitative, for, if falling dilutions of virus are added to equal amounts of undiluted immune serum, a point is reached at which the mixture can no longer be reactivated or dissociated by simple dilution. Mixtures, separately prepared before incubation at 37 C, and containing dilutions of virus and immune serum equivalent to those derived, after incubation, by decimal dilution of a nondissociable mixture of undiluted immune serum and virus, were active when inoculated intraperitoneally. Certain mixtures of Rift Valley fever virus and immune serum, apparently neutral when injected intraperitoneally, can be reactivated by intranasal instillation. This phenomenon is also quantitative and can be demonstrated only with those serum-virus mixtures that can be reactivated by simple dilution. Certain mixtures of Rift Valley fever virus and immune serum, apparently neutral when injected intraperitoneally in doses of 0.4 cc are found to be active when injected intraperitoneally in doses of 0.03 cc. This phenomenon is also quantitative and can be demonstrated only with those serum-virus mixtures that can be reactivated by simple dilution. The reactivation of an apparently neutral mixture by intranasal instillation is probably due not so much to the route of inoculation as to the small quantity of the inoculum. Evidence is brought forward to show that mice which have survived an injection of virus and immune serum are immunized only when the amount of virus in the mixture injected exceeds a certain minimum. The author gives the following hypothesis in explanation of the foregoing facts. When a large inoculum of immune serum and virus is injected, a certain number of cells are immediately invaded by the virus, which proceeds to grow in these cells. Virus will be liberated from these cells, and at the same time immune bodies will be produced from the tissues. Virus so liberated meets with the immune bodies present in the serum and, provided the proportion of immune bodies and virus is correct, there forms a nondissociable mixture. The immune bodies are provided both by the foreign serum originally injected and the immune bodies formed from the animal's own tissues. As the passively injected immune bodies are excreted, the actively produced immune bodies take their place, and thus a balance is struck between the amount of virus and the amount of immune bodies. Death does not

take place. When a small quantity of virus and immune body is inoculated, the same process occurs as before but now the small amount of passively injected immune bodies disappears more rapidly from the circulation, while the small amount of virus produces in the same time a comparatively small amount of immune body. A point is thus reached at which there is no longer any passive immune body left and the amount of active immune body is small. Virus is therefore present in an active condition, and death can occur.

Incomplete Rupture of Sclera—Tillema cites two cases of incomplete rupture of the sclera in which the pathologic changes observed in the inner layers of the sclera may have arisen through the raised intra-ocular pressure causing a staphyloma of the sclera, and through a partial rupture of the sclera. The microscopic observations are based on partial rupture of the sclera. Two different types of rupture were found: a typical rupture near the corneal limbus in the first case and an equatorial (i. e., atypical) rupture in both cases. Only the cases of von Szily, Fuchs and Burk are described in sufficient detail to warrant a sure diagnosis. All three cases constitute typical, incomplete ruptures of the sclera. To this small number of incomplete, typical ruptures the author adds the anterior rupture in his first case bringing the total up to four. As atypical, incomplete ruptures have not yet been recorded, his two instances of incomplete, equatorial rupture are new. In both cases mainly the inner layers of the sclera were affected. This agrees with what is known of ruptures in general. Although the literature yields no other cases of this type, he believes that it is not so rare as this would suggest. Garner (1891) gives a detailed description of traumatic glaucoma in a young boy whose eye had to be removed two weeks after the accident. Within this short period a staphyloma had developed superiorly and medially at the equator. If glaucoma had been the cause of distention of the sclera, one would expect the sclera to distend generally, as in cases of buphthalmos. As in Garner's case a staphyloma developed within two weeks after a blow, it is reasonable to suspect a traumatic lesion to the sclera. Moreover, the staphyloma developed superiorly and medially, and in the present cases pathologic changes were most marked in the same region. The majority of scleral ruptures occur upward and inward.

Thoracoplasty in Treatment of Pulmonary Tuberculosis—In considering what type of cases are likely to be benefited by thoracoplasty, Young emphasizes the fundamental fact that thoracoplasty affects directly only a local area of the lung, whereas pulmonary tuberculosis affects the whole body. In every case of active pulmonary tuberculosis, in addition to the obvious diseased areas, tubercle bacilli are present in apparently healthy areas of the lung in mediastinal glands and intermittently in the blood stream. Thoracoplasty should be considered in all cases of pulmonary tuberculosis which have not achieved arrest of the disease by other means, but before recommending a thoracoplasty in any case the following conditions must be satisfied: 1. The lesion for which it is proposed must be the type that will heal if mechanical impediments

are removed, and the thoracoplasty must be likely to remove them. 2. If lesions are present in the other lung they must be "inactive." 3. Fresh "flares" in apparently healthy areas must be improbable. 4. The patient must be fit for the operation. 5. The patient must have reached the most favorable moment for the operation. 6. Technical conditions must be satisfactory. 7. The functional result is all that matters to the patient, so it must be clear that a good functional result will be obtained. The effects of a thoracoplasty are not the same as those of a complete artificial pneumothorax. A successful artificial pneumothorax is more efficient and less dangerous than a thoracoplasty and should always be tried before a thoracoplasty but should not be persisted with if inefficient. Thoracoplasty represents the last stage in the active treatment of any tuberculous lesion in the lung. An error made in the selection of the case or the stage in the disease when the operation is performed can never be repaired, but in no form of treatment will skilled collaboration between the physician and the surgeon be more amply repaid.

Postabortal and Puerperal Gas Gangrene—Hill observed thirty cases of postabortal and puerperal gas gangrene between April 1933 and February 1935. Of the thirty cases, twenty-two were associated with abortion (postabortal) and eight with labor at term or near term (puerperal). From twenty-two *Clostridium Welchii* and from two *Vibrio septique* were recovered from the tissues during life. The mortality was 63 per cent. The considerable frequency of this dread infection, which is protean in its manifestations and of recently increased incidence in Melbourne is indicated. The fundamental importance of early diagnosis is emphasized. The clinical features of the various types have been outlined systematized and, when this was thought to be of value, classified in an attempt to achieve clarity and assist early recognition. The principles underlying successful treatment are early diagnosis, early elimination of the primary focus and immediate and massive serologic and general therapy. The author suggests that during early pregnancy the uterine blood vessels have a relatively small caliber and that venous thrombosis as a result of endothelial damage by the *Clostridium Welchii* toxin is particularly likely. In the uterus engorged with blood clot the organisms find a rich and undisturbed pabulum in which growth and hemolysis proceed apace. In the later weeks of pregnancy, on the other hand, the uterine muscle is greatly hypertrophied and the caliber of its vessels is enormously increased. A more massive muscle infection and a greater rate of toxic and organismal absorption are now possible. But, in keeping with the increased blood supply and the diminished frictional resistance in the large venous channels, thrombosis, and with it hemolysis, are much less liable to occur. It is possible that in some cases of overwhelming infection thrombosis may be forestalled by death. In skeletal muscle infection, as Toombs suggested, the relatively poorer vascular and lymphatic supply apparently accounts for the comparative rarity of general hemolytic phenomena. Finally, to the *Clostridium Welchii* toxin as a whole may be attributed that state of collapse and peripheral circulatory failure which is the terminal feature of fatal cases and the result, as Topley and Wilson have pointed out, of the deleterious action of the toxin on the adrenals.

Ultraviolet Irradiation as Prophylactic for Cracked Nipples—For two or three years MacLellan treated cracked and painful nipples that occur in the last month of pregnancy

by exposure to air. A warm flannel cover for the breast with two small apertures to permit exposure was provided. There seemed to be a decided improvement. This suggested the use of the ultraviolet ray as a prophylactic agent. From six to eight treatments, depending on whether the patient is of the blond or brunette type, have been employed for the last two years. The treatment is started with one and a half minutes' exposure at 40 inches and given three times a week, working up to ten minutes' exposure per treatment. Only the nipple and areola are exposed. Since this treatment was started, in not one instance has there been even the slightest trouble, some fifty patients having been treated.

Observations on Excretion of Cevitamic Acid—Observations after a single test dose undoubtedly show that a deficiency of cevitic acid exists, but they do not, in the opinion of Archer and Graham, give such full information as to the amount of cevitic acid which must be given before the percentage output rises above 75. In their case of scurvy the significant rise in the excretion occurred when 1700 mg. had been given in comparison with 600 mg. in Johnson and Zilva's case with 1,200 mg. in a test case and with 1,400 mg. in Harris and Rays case. This is a very small difference, and it would be difficult to know where to draw a line between scurvy and a potential case of scurvy and a case of vitamin C subnutrition. The percentage output in Johnson and Zilva's case rose to 56 per cent after 1,360 mg. and to 87 per cent after 1,480 mg. had been given, in Harris and Rays case it rose to 77 per cent after only 1,480 mg. had been given and in the authors test case, although it reached 48 per cent after 1,600 mg. had been ingested it did not reach 75 per cent until 3,200 mg. had been taken. The percentage output did not exceed 53 per cent even after 4,950 mg. had been ingested. The observation suggests that the percentage output is much more valuable evidence that a patient has scurvy than the amount of cevitic acid taken before the excretion increased, or the amount excreted after a test dose.

Treatment of Urinary Infections—Holling and Platt used mandelic acid in the treatment of twenty-nine patients suffering from urinary infections. Catheter specimens of urine were first examined to determine the nature of the infection, and pyelography (retrograde or intravenous) was performed, when necessary, to exclude pyonephrosis, calculus or tuberculosis. The first few patients were given mandelic acid, neutralized by sodium bicarbonate as described by Rosenheim. Later 3.2 Gm. of sodium mandelate, 4 Gm. of syrup of orange and enough water to make 30 cc. were prescribed in water four times a day. This was preceded by 2 Gm. of ammonium chloride and 1 cc. of liquid extract of liquorice in enough water to make 30 cc. given four times a day. During treatment daily fluid intake was restricted to 2 pints (1 liter) unless thirst was complained of, when more fluid was allowed. The acidity of the urine, which must attain a pH of 5.3 or less was tested by the addition of 5 drops of methyl red solution

to 2 cc. of urine. Specimens of urine were examined at intervals of two days when possible. When the deposit (examined as a wet film) showed only a few leukocytes and no bacilli, cultures were again made from catheter specimens. In every uncomplicated case of acute or chronic pyelonephritis the urine was rendered sterile by mandelic acid treatment in from two to twenty-one days. There were five failures, in cases that were really not suitable for mandelic acid treatment. During treatment a few casts and a trace of albumin occasionally occur in the urine. The treatment is obviously unsuitable in the presence of renal insufficiency because badly damaged kidneys cannot excrete a sufficiently acid urine or a sufficient concentration of mandelic acid. Nevertheless the presence of nephritis in an earlier stage does not appear to be a contraindication. The only disadvantage of mandelic acid treatment is the necessity of giving two somewhat unpleasant medicaments, one followed closely by the other, four times in the day. To obviate these disadvantages if possible, the authors tried the acidifying effect of elvir of ammonium mandelate on themselves and found that doses of 34 grains (2.2 Gm.) of ammonium mandelate four times daily produced a satisfactory urinary acidity (pH 5.3) within an hour or two but that this degree of acidity was not invariably maintained throughout the day. Therefore, they concluded that somewhat larger doses should be given. Four patients were treated with ammonium mandelate, and in all four a sterile urine was obtained in a week or less, though all had a chronic infection. On the basis of their experience, together with what is already known of mandelic acid treatment, they feel justified in saying that ammonium mandelate is a convenient means of administering mandelic acid and that in the majority of cases the use of ammonium chloride can thereby be obviated. The suitable dose of ammonium mandelate is probably the same as that of the sodium salt.

X-Ray Appearances of Lungs of Electric Arc Welders

—Doig and McLaughlin declare that chronic pulmonary lesions directly associated with the occupation have not been recorded up to the present time as occurring in electric arc welders. The results of a clinical and roentgen examination of the chests of sixteen electric arc welders are presented. They are apparently healthy men and are actively engaged at their occupation. Nearly all were apprenticed to electric welding at 14 years of age and have worked at no other trade. The roentgenograms of six show a generalized fine mottling over both lung fields, the remaining roentgenograms show less marked changes, but none could be considered a picture of a completely normal chest. The conditions that have to be considered in the differential diagnosis include miliary tuberculosis, asbestosis, silicosis and other pulmonary conditions caused by dust or fumes. The authors are not prepared to be dogmatic about the interpretation of the roentgenographic and clinical observations, especially because no opportunity for histologic examination of the lungs has arisen. Little doubt exists, however, that the changes in the lungs have been brought about in these men by the dust or fume which they have inhaled while working. During welding operations, dense white or grayish white fume rises up continuously from the spot that is being welded. The fume is made up of the volatilized constituents of the coverings of the rods together with fine particles of oxidized metal, usually in the form of iron oxides. In addition the fumes probably contain gases such as nitrogen peroxide and ozone, which are formed by the action of an electric spark on the air. The composition of the coverings of the electrodes is usually sodium silicate. The coverings of a certain type of electrode contain asbestos. The rods are sometimes dipped in a mixture containing powdered asbestos and sodium silicate, or asbestos yarn is wound round the rod and fixed by sodium silicate. In some cases the asbestos completely covers the rods, and in others it is merely a cord which is wound spirally about the rod. The roentgen appearances in the well marked cases differ from the usual picture of asbestosis. In none of the positive cases and in only one of the suggestive cases was there any blurring of the diaphragmatic shadow, and in no case was the heart outline blurred. The line of the interlobar septum was seen in only one positive case. The upper lung fields appear to be the earliest, and in established cases most markedly, affected. Before asbestosis can be eliminated from the differential diag-

nosis it must be remembered that the asbestos fibers are being subjected to intense heat and are not in the same physical state as the fibers which are inhaled by workers in an asbestos factory. It is possible that an atypical picture of asbestosis might be produced by the inhalation of altered asbestos. The roentgen appearances resembles those of a fine silicosis, but the clinical features show two important differences. 1 The electric welders examined are in good health and are fit to work. The only symptoms observed were slight cough and morning expectoration. None of the men suffer from dyspnea. 2 None of them have concomitant pulmonary tuberculosis. Military tuberculosis can be ruled out of the differential diagnosis for clinical reasons, and to some extent on the x-ray appearances.

- *Treatment of Patients Infested with *Taenia Saginata* with Especial Reference to Certain Unusual Results. H. B. Penfold—p. 385
Surgical Treatment of Carcinoma of Thoracic Esophagus. E. S. J. King—p. 399

Treatment of Patients Infested with *Taenia Saginata*—Penfold declares that by the use of large but safe doses of liquid extract of male fern approximately 90 per cent of cases of *Taenia saginata* infestation can be cured by one treatment. The combined results of the treatment of both children and adults were seventy-seven cures in his eighty-six cases treated for the first time. Eight of the nine patients treated a second time were cured while the result in the remaining case is doubtful. There is no reason to suppose that when the drug fails on the first occasion it is because the worm is unduly resistant to it, for, if this were so, the percentage of successes on the second treatment would be much less than on the first treatment which has not been found to be the case. This suggests that changing the anthelmintic if the first treatment is not successful, is not warranted. The treatment is simple, but it must be carried out with care, since the effective therapeutic dose is not much less than the toxic dose. The main factors for successful treatment are adequate preparation of the patient and the administration of an adequate dose of an active extract of male fern in such a manner that the chance of vomiting is reduced to a minimum. To prevent the toxic effects of liquid extract of male fern, which may be fatal, an overdose should not be given and it should be made certain that the intestine is well evacuated for from four to five hours after administration of the anthelmintic. In almost all cases of infestation, whether single or multiple it can confidently be asserted that the major portions of all the worms present will be expelled, provided the recommended total dose, 10.7 cc. of an active male fern extract, has been administered and not vomited. After administration of liquid extract of male fern the worms harbored by some patients cannot be expelled by purgatives, although they cease to live and are apparently digested. Patients from whom the head of the worm has not been found should not be retreated unless segments reappear. The immediate treatment is not materially altered by the discovery of the head, and therefore, to save time, a search for it might be omitted.

*Cerebral Pseudotumors. T. de Martel, J. Guillaume and R. Thurel—p. 563

Cerebral Pseudotumors—According to de Martel and his collaborators, the partitions of the subarachnoid space and the ventricular cavities can produce syndromes analogous to those of cerebral tumors and by means of the same physiopathologic processes. They consider in some detail circumscribed serous leptomeningitis, which is unilateral and occupies the lesser convexity of the antero-cerebral fossa. These lesions produce the symptoms of tumor such as headache, frequent vomiting and epileptic attacks, central facial paralysis, brachio-plegia and hemiparesis, especially of the brachiofacial region, and aphasia and amnesia are commonly present. Diffuse intracranial hypertension is usually absent. The results of surgical intervention which consists in the simple evacuation of the serous collections demonstrate the site of compression in the production of pseudocortical lesions. Thanks to encephalography after injection of air by lumbar puncture or ventricular puncture localized lesions in the foramen of Monro can be recognized. The best therapeutic measure for this lesion consists in interrupting the septum lucidum, which allows emptying into the lateral ventricle and thus into the third ventricle. Pseudotumors of the posterior cerebral fossa are characterized by headache predominating in the occipital region, vomiting disorders of equilibrium and the usually increased cerebrospinal pressure. Usually the condition can also be relieved by operation. Finally the authors discuss arachnoiditis of the optic chiasm. In all the described conditions the symptoms closely resemble a tumor of the same region and frequently the preoperative differential diagnosis is difficult. Surgical treatment, as a rule, is highly successful.

Hemiplegia of Cardiac Patients. J. A. Chavany—p. 587
*Success of New Treatment of Hemorrhagic Diathesis. J. R. Dreyfus—p. 589

Treatment of Hemorrhagic Diathesis—In the opinion of Dreyfus, hemorrhagic diatheses include all those diseases which show a syndrome with a tendency to cutaneous, mucosal or visceral hemorrhages. Hemophilia, fibrinopenia and purpura of infectious origin are not included. Examples of several cases of hemorrhagic diathesis are illustrated by case reports. The marked improvement that occurred in these patients as a result of parenteral administration of vitamin C was striking. The author speculates as to the mechanism of action of ascorbic acid and liver extract when administered parenterally and its favorable effect on the hemorrhagic diathesis. No conclusions can be drawn, but the author believes that there is no doubt concerning the practical efficacy of vitamin C administration, especially parenterally.

*Importance of Auricular Sounds in Normal and Pathologic States. E. Braun Menendez and O. Orias—p. 603

Auricular Sounds in Normal and Pathologic Conditions—Braun Menendez and Orias studied graphically the appearance of the auricular sounds. They concluded that the auricular contraction produces this sound constantly. It seems to be composed of vibrations originating in the auricle during systole and of vibrations produced in the ventricle by the action of blood forced out by the auricular systole. The auricular vibrations form the initial oscillation of the first heart sound. The auricular sound considered an acoustic phenomenon independent of the first heart sound can be heard and constantly recorded by way of the esophagus. Over the precordium it can be frequently found in infants and in 20 per cent of the young adults. The auricular sound is the most common cause of sounds that are diagnosed by auscultation as reduplication of the first sound. Furthermore the auricular sound can be

intensified by auricular hypertrophy, by increase in the blood volume forced out by the auricle, or by diastolic ventricular hypotonia

Acute Peritoneal Involvement in Liver Abscess—Huard and May report three cases in which symptoms of acute peritonitis occurred during the course of abscesses of the right hepatic lobe. The resultant syndrome is characterized by a sudden onset developing while the patient is in good health or after some vague digestive prodromal symptoms followed by an intense acute pain in the right hypochondrium accompanied by a contracture of the epigastrium. The clinical course varies. The pathogenesis is not well understood and the authors do not know to what degree the peritoneum is involved or whether the disorder is spread there by means of a lymphangitis. Further clarification of this clinical syndrome is desirable.

*Some Effects of Intra Arterial Injections P Huet and D Bargeton—p 677

Intra-Arterial Injections—Huet and Bargeton believe that the general toxicity of a substance is less when it is introduced intra-arterially than intravenously. To determine more precisely the reactions to an intra-arterial injection the authors carried out investigations on dogs anesthetized by chloral hydrate. The injections were made in the peripheral end of the left femoral artery in the opposite femoral artery or in the axillary humeral artery. Observations on the general blood pressure and the blood pressure distal to the site of injection were recorded with the aid of a kymograph. Various solutions were used. The authors concluded that isotonic solutions did not affect the central pressure and had no effect or only an insignificant one on the recurrent pressure. Hypotonic solutions did not affect the central pressure but caused an initial hypertension followed by a considerable drop in pressure in the peripheral region. Hypertonic solutions caused general hypertension but a severe and lasting hypotension later in the peripheral circulation. The hydrogen ion concentration of the solutions also was of some significance. When the pH was less than 7, marked changes in the peripheral pressure were noted. These factors should be of importance in choosing substances for intra-arterial injection though much further work remains to be done.

Lymphatic Vessels in Pulmonary Tuberculosis—Arloing and Berthet injected a culture of virulent tubercle bacilli diluted 1:10,000 into the right paratracheal ganglion or the conjunctival culdesac of guinea pigs. The animals were killed from several days to several weeks after the injection. In the animals examined several months after the inoculation a generalized infection of all the organs with multiple fibrocaseous nodular lesions was noted. In the animals killed between five and twenty days after the inoculation lesions of the stroma and peribronchitis characterized by infiltration of the interalveolar tissue with histiocytes were found. In cases in

which India ink had been added to the infectious material the particles of ink were found in the form of black granulations in the protoplasm of some histiocytes of the stroma. The fact that all the lesions were bilateral suggested that the dispersion of bacilli was generally both by the lymphatic and by the blood channels. The authors concluded that lesions of the stroma preceded those of the alveoli. It is certain that the route of penetration of bacilli plays a part in the determination of the anatomoclinical form of the tuberculosis but other factors enter equally, especially those of resistance and bacillary virulence.

Pleural and Pulmonary Suppurations with Persistent Cavitation—Curtillet stresses the importance of systematic examinations of the lungs with iodized poppy-seed oil after the apparent clinical cure of bronchiectasis or cavitation. In many instances these examinations will reveal the presence of a persisting cavity and furthermore aid in the determination of the method of disappearance of the cavity. Evidence points to the decrease in the size of the cavity and sometimes its eventual disappearance by epithelization. Since this is apparently the normal method of recovery, the author believes that demonstration of a persistent cavity may lead to rational intervention by means of closure of the persisting fistula. Since the result of this procedure is epithelization, it cannot be said to interfere with the normal method of healing.

Medical Treatment of Epileptic Conditions A Ulrich—p 444

*Bee Venom Therapy M Kosier—p 447

Insulin Sensitivity—Rathery and his associates emphasize that each person reacts in his own manner to insulin. For this reason it is impossible to base insulin dosage on the degree of reduction of glycemia produced by insulin in rabbits or on a fixed rate of utilization by insulin of a certain quantity of carbohydrates. The authors point out that there are some cases of diabetes which are resistant to insulin whereas others have a hypersensitivity to insulin. They differentiate between permanent and intermittent hypersensitivity to insulin. They show that their observations on hypersensitivity to insulin are of therapeutic importance in that they demonstrate the importance of constant control of diabetic patients undergoing insulin treatment.

Bee Venom Therapy—Kosier resorts to the injection of bee venom particularly in cases that do not respond to the usual medicinal and physical therapy. He uses it in all forms of arthritis particularly in the subacute and chronic forms also in arthritis deformans periarthritis myalgias, neuralgias and neuritides. However, he considers the treatment contraindicated in patients with high fever or tuberculosis, that is, in those in whom all forms of irritation therapy are to be avoided. He injects it intracutaneously into the dorsal sides of the extremities or the trunk or into the skin of the diseased joints. He advises against the injection into the volar side of the extremities, because the edema might assume large dimensions in case of severe local reaction. The neighborhood of the neck should likewise be avoided. The doses have to be adapted to the individual case but the first dose is usually 0.05 cc. In case of severe local reaction the same dose is repeated after three or four days and after that the doses are gradually increased by 0.05 cc. In patients who are less sensitive, 0.1 0.2 0.3 0.4 and up to a maximum of 0.5 cc are given at intervals of three or four days. In all the patient is given from five to eight injections. In order to avoid necrosis of the skin, not more than 0.1 or 0.15 cc should be deposited in one puncture. The local reaction may be slight or severe. General reactions are extremely rare. The author gives the clinical histories of some of the patients and a tabular report of the results he has obtained in sixty-six cases. He obtained the best results in arthritis deformans, humeroscapular periarthritis and various neuralgias and myalgias.

Idiopathic Pyloric Hypertrophy in Adults—Donati reports two cases of pure pyloric hypertrophy in women aged 28 and 40, respectively. The author states that the disease is more frequent in women than in men. From early life the patients show recurrent gastric disturbances, which become intensified as the condition develops. The clinical diagnosis, especially of atypical benign forms is difficult. When the disease is already developed, the clinical symptoms and objective and roentgen signs are those of pyloric stenosis due to ulcer. The anatomic lesion involves the muscular layers of the pylorus without involving the layers of the gastric wall. Pure pyloric hypertrophy is entirely different from inflammatory and sclerous neoplastic and myomatous forms of pyloric hypertrophy. It is equivalent in adults to pyloric hypertrophy in infants. Certain zones around the pylorus are more intensely involved than others in the pure hypertrophic process. Both congenital and acquired factors, especially those related to the production of pyloric spasm, are involved in the pathogenesis. The treatment is surgical, especially in grave cases complicated by emaciation. The rather frequent finding of the condition at necropsy proves that the disease is not as rare as has been believed.

 Bismuth Treatment in Acute Tonsillitis J. M. Tato and V. E. R. Carro—p. 955

Roentgen Irradiations in Treatment of Hypertrichosis—Niseggi and Vierheller advise roentgen irradiations in the treatment of hypertrichosis. The irradiations are given with a relatively soft beam of rays of between 60 and 120 kilovolts through a 1 mm. aluminum filter. It is advisable to divide the irradiation area into small fields with a maximal space of 10 by 15 mm. per field. The irradiations are given once a month. The first irradiation is 70 per cent of the skin erythema dose, which is calculated at 800 roentgen units including diffuse rays. The following doses are 60 per cent of the erythema dose. As a rule, six irradiations complete the treatment which produces complete and permanent depilation. The treatment is harmless. In certain cases it causes temporary irritation of the skin or other local disturbances which disappear in about twenty-four or thirty-six hours. The patients treated by the author have been seen some time after completion of the treatment. In all cases the treatment left no marks and the growing of superfluous hair never returned.

Pseudo-Ascites—Vallejos Meana describes under the name of pseudo ascites a rare syndrome, which is similar to typical ascites but of different pathogenesis. The syndrome consists in an extraperitoneal abundant accumulation of pseudo-ascitic fluid, located between the fascia transversalis and the anterior layer of the parietal peritoneum, which is repelled inward together with the abdominal and pelvic organs enclosed by it. The fluid may be hematic, purulent, urinary or a mixture of these, according to the etiology. It forms and reproduces itself rapidly and in the florid period of the disease it occupies extraperitoneally about three fourths of the abdominal cavity from one to another of the parietocolic spaces and from the pelvis

to the epigastric region. The syndrome is the result of a tumoral renal process (adenocarcinoma in the case of the author), which produces alterations of the parenchyma, perinephric hemorrhage, ureteral obstruction, infiltration and contamination of the perirenal fat, rupture of the anterior layer of the renal fascia by intrapelvic pressure of a purulent fluid, formation of pseudo ascitic fluid between the fascia transversalis and the parietal peritoneum, and dissociation of the two structures. The syndrome follows an apparently benign evolution during the first and second periods, in which clinical diagnosis is difficult, although it can be made by the following signs and symptoms. In the early period, which corresponds to the onset of the renal intrapelvic and urinary disturbances, the patient complains of general malaise and intermittent slight renal pain. In the second period, which corresponds to the formation of the effusion, the symptoms increase although they are never intense. The renal tumor can be felt by palpation and the accumulation of the pseudo ascitic effusion is already noticeable at the iliac fossa of the side of the pathologic kidney. The third period is grave. The clinical picture is that of typical ascites. Pseudo-ascites can be differentiated from the several forms of ascites of liver cirrhosis by the asymmetry of the abdomen, which is more prominent on the side of the pathologic kidney, asymmetry of the area of dullness on percussion, late appearance of collateral circulation at the flanks, and especially by the nature of the pseudo ascitic fluid obtained at the first puncture. While the fluid in cirrhotic ascites is a transudate, the pseudo-ascitic fluid is not, and in a large number of cases it contains urinary constituents, such as urea, chlorides and sediment. The treatment consists in evacuation of the fluid and nephrectomy. One case is reported.

Lambliasis—Ibarrola Solano states that in the majority of cases the lamblas live in the duodenum or first part of the jejunum, in exceptional cases they penetrate the gallbladder. Lamblias may exist in the intestine of normal persons without causing symptoms, but in other cases they produce intestinal gallbladder, hepatic, or gastric disturbances. The intensity of the disturbances is related to the number of infesting parasites. The most frequent symptoms are diarrhea, fever, headache, anorexia, allergic reactions and loss of weight due to the absorption of toxic metabolic products of the parasites. The toxemia is harmful to the bone marrow, as shown by blood changes. Lymphocytosis and eosinophilia are the most frequent changes. Intravenous or intraduodenal injections of arsenicals, associated with drainage of the gallbladder are the best treatment. The intravenous treatment consists of injections of arsphenamine in doses of from 0.03 to 0.06 Gm. per injection. The number of injections depends on the extermination of the parasites, which is proved by their absence in the duodenal and biliary secretions obtained by duodenal drainage after intraduodenal injection of a 33 per cent solution of magnesium sulfate. The total dose of arsphenamine during the entire treatment does not exceed 1 or 1.8 Gm. The intraduodenal treatment consists of two injections of arsphenamine in doses of 0.03 and 0.06 Gm. respectively, dissolved in 200 cc. of distilled water, given with an interval of five days between injections. The intravenous or intraduodenal treatment is associated with drainage of the gallbladder stimulated by the injection of a 33 per cent solution of magnesium sulfate through the duodenal catheter. Eleven cases are reported.

Role of Tuberculosis in Marriage L Vajda —p 713

Local Differences in Allergy—Brings-Waldstein says that it has been known that the cutaneous allergy for tuberculin is not the same all over the body. She cites reports which corroborate this and also shows that the outcome of the cutaneous tests has considerable diagnostic significance. Her investigations aimed at determining whether there is a difference in the intensity of the cutaneous reactions on the two sides of the thorax in patients with unilateral pulmonary and glandular processes. In children with unilateral processes, Mantoux tests were made with various concentrations and on different sites. It was found that the allergy is extremely intense in children with tuberculous pulmonary and glandular processes without cavernous disintegration for it is possible to produce reactions with greatly diluted tuberculin solutions. In cases with tuberculosis of the hilus glands, secondary infiltration and pleurisy, there is no difference in the allergy of the "healthy" and the diseased side. In children with pulmonary and glandular processes that have a tendency to heal, the allergy is greater over the diseased than over the healthy organ, in processes without a healing tendency, the allergy is less intense over the diseased organ than over the healthy one, or it is the same over the two. This shows that the allergy test is helpful in determining the prognosis.

Primary Tuberculous Focus at Vaginal Introitus—Hüseyin reports the case of a woman, aged 25, with a negative anamnesis as regards tuberculosis, who developed the first symptoms (fatigue, chills) one month after marriage. Subsequently she developed leukorrhea, and swelling of the labia and of the inguinal glands. The ulceration of the vagina was repeatedly examined for spirochetes, but none could be found. The pus of suppurating lymph nodes was examined on Löwenstein's culture medium and by the animal test, and in both cases the results indicated tuberculosis. Roentgenoscopy of the lungs of the woman disclosed no signs of tuberculosis. Since the vaginal ulcer originated at the hymenal tear and since the regional lymph nodes became rapidly involved, the thought of a primary infection seems justified. Development of the process immediately after marriage suggested that the husband might be the source of the infection. His examination disclosed an open pulmonary process and bacilli in the sputum.

*Maggot Treatment of Chronic Osteomyelitis H J Lang —p 406

Treatment of Perforation of Gastroduodenal Ulcer—Gatersleben and Zitzmann report for a period of eight years forty-two cases of perforation of gastroduodenal ulcer in which operation was performed. Their immediate mortality amounted to 23.8 per cent. The authors were able to follow up thirty patients. The best immediate as well as late results were obtained with partial gastric resection. This operation, however, could be applied only in a small number of carefully selected cases. The authors practiced a simple suture of the perforation in all cases not suited for the formidable operation of partial gastric resection. The results were quite satisfactory. Poorest results were obtained when a gastro-enterostomy was added to the suture of the perforation. The authors therefore feel that the latter should be entirely abandoned.

Maggot Treatment of Chronic Osteomyelitis—According to Lang, maggot therapy, as applied in the Third Surgical clinic of the University of Berlin in cases of chronic osteo-

myelitis, demonstrated beyond doubt the favorable influence of live maggots on necrotic tissues. The wounds rapidly take on a clean appearance and display fresh healthy granulations. Baer's "living antiseptics" proved to be effective in cases of chronic osteomyelitis which had resisted other therapeutic methods. The author doubts the possibility of successfully substituting an extract of maggots for the living maggots and their enzymes.

*Roentgen Irradiation as Method of Choice in Beginning Puerperal Mastitis W H Hanne —p 683

Roentgen Irradiation in Beginning Puerperal Mastitis—Observations in thirty cases convinced Hanne that roentgen irradiation is the method of choice in incipient puerperal mastitis. He always applied 20 per cent of the unit skin dose at a tension of 170 kilovolts, with a filter of 0.5 mm of copper and 0.5 mm of aluminum and a focus skin distance of 30 cm. Depending on the extent of the inflamed area the fields were 6 by 8 or 10 by 15 cm. This treatment was always successful and an incision was never necessary. The author rejects the use of 40 per cent of the unit skin dose because he found that 20 per cent of the dose produced the desired results and preserved the lactation capacity of the women, which is not possible if 40 per cent of the unit skin dose is given. To be sure, even the smaller dosage impairs the milk secretion somewhat for, although the milk secretion of the irradiated breast increases again after five or eight days, it does not reach the yield of the nonirradiated breast.

Antithyroid Action of Adrenal Cortex—Oehme investigated adrenal cortex extract for its inhibiting effect on the action of the thyroid or of thyroxine. He found that an adrenal cortex extract which was free from cevitic acid suppresses to some extent the chronic hyperthyroidism that is induced in guinea-pigs, the increase in the basal metabolic rate produced by the daily administration of thyroxine is slight or entirely absent if adrenal cortex extract is given at the same time. The author was able to corroborate that cevitic acid has practically the same effect. He concludes from these observations that the adrenal cortex contains two antithyroid substances, which are not identical with vitamin A or with tyrosine. The reduction of the action of thyroxine by means of tyrosine could likewise be corroborated. In studies on the newly discovered antithyroid principle of the adrenal cortex it was found that it is destroyed if it is exposed for from one to two hours to a stream of oxygen at a *pH* of 9.3 and a temperature of 38 C (100.4 F). It does not prevent the histologically demonstrable activation of the thyroid by the thyrotropic hormone of the anterior lobe of the hypophysis. The author discusses the role of the adrenal cortex in the pathogenesis and treatment of hyperthyroidism.

Significance of Tyrosine in Urine—Weiss points out that degenerative processes in the liver lead to the elimination of tyrosine in the urine. However, since the method of demonstration formerly in use was rather complicated, the occurrence of tyrosine in the urine did not attain the diagnostic and prognostic significance it deserves. The author describes a method which has the advantage of greater simplicity and sensitivity and of a nearly absolute specificity. The test is based on the fact that tyrosine (as well as the frequently accompanying

leucine) is precipitated by alcohol. The author mixes 20 cc of urine, either in its native acidity or following slight acidification with acetic acid, after simple filtration, with 60 cc of concentrated alcohol. After this mixture has been left standing for two hours, typical tyrosine crystals can be seen in the settled sediment of the urine of many patients with liver disease. After a little while the sediment is filtered off and washed once or twice with alcohol. The residue is dissolved in 3 cc of a 2 per cent lye solution and after slight acidification with two drops of glacial acetic acid Millon's test is made. If tyrosine is present slight warming or fifteen minutes of cold storage will produce a noticeable red coloration of the fluid. In cases with a considerable amount of protein sediment this may become red, however proof of a positive tyrosine reaction is the red coloration of the fluid standing above it, provided of course the presence of medicaments (salicylates) can be excluded. Millon's reaction is usually positive when tyrosine crystals are present. The microscopic demonstration of tyrosine is even better than the chemical test. The tyrosine crystals have a characteristic appearance. The author reproduces a photomicrograph of leucine spheres and tyrosine crystals. To be sure, in the presence of large amounts of other crystallizing substances, there is the possibility that the tyrosine crystals are covered up. For this reason it is advisable if there are strongly positive chloride and protein reactions to extract these substances first and to make a search for tyrosine crystals only in the second precipitate. The author found the examination of the urine for the presence of tyrosine (and leucine) by means of this method helpful in the estimation of the condition of the liver in various disorders. In the majority of the examined cases, tyrosine was an accompanying symptom of hepatic disorders. It was found not only in the severe forms but also frequently in the milder forms, and it was sometimes absent in the severe disorders (cirrhosis of the liver and catarrhal icterus). However, it is nearly always detectable during an acute attack in gallstone disease and in some pancreatic disorders, particularly those that are accompanied by gallstone disease. The author admits that tyrosine and leucine are never pathognomonic for a disease, nevertheless he regards his test as valuable in diseases of the liver.

Hypoglycemia in Patients with Gastric Diseases—Straaten and Hünemann point out that the postoperative disturbances represent a difficult problem in gastric surgery. Investigations in recent years disclosed that the blood sugar conditions play an important part. The disturbances in the blood sugar curve after oral sugar tolerance tests throw more light on the estimation of postoperative disturbances after gastric resection. The authors decided to investigate to what extent the changed carbohydrate metabolism and particularly hypoglycemic conditions are responsible for the postoperative difficulties after operations on the stomach. They describe their observations in the course of sugar tolerance tests on forty-eight patients. They found that the hypoglycemic reaction after sugar consumption is not a reaction that is specific for the stomach that has been operated on. It occurs in patients who have undergone gastric operations in patients with ulcer or gastritis who have not been subjected to surgery

and in other diseases, particularly during the period of convalescence. The authors discuss the causes of the alimentary hypoglycemia in patients with gastric diseases and in those having undergone surgical interventions on the stomach. They think that vagotomy, the condition during convalescence and especially the changed resorption mechanism are responsible. The mechanism of resorption may be altered in gastritis, duodenitis and jejunitis and because of changes in evacuation. They say that the individual hypoglycemic attack can be counteracted by the administration of dextrose. The predisposition to hypoglycemia is best influenced by frequent small meals and by not onesidedly preferring carbohydrates. The use of a special surgical technique to produce evacuation mechanisms that resemble the normal ones will prevent the hypoglycemic reaction in many cases. Von Haberer's technique of gastric resection largely fulfills these requirements.

Acid Secretion of Stomach in Hyperthyroidism—The Syllas call attention to the fact that gastro-intestinal disturbances are comparatively frequent in hyperthyroidism. They subjected seventy-four patients with exophthalmic goiter to fractional withdrawal of the gastric contents after a caffeine test drink and detected acidity in 50 per cent of these cases. They consider the inhibiting action of the overstimulated sympathetic the cause of the reduced gastric secretion. They reject a relationship to pernicious anemia. A connection between acidity and the diarrhea that occur in patients with exophthalmic goiter could be proved in only a few of the cases. The authors think that it is advisable to examine the gastric juice from time to time in patients with exophthalmic goiter.

Dangers of Iodine Therapy in Lead Poisoning—Fellinger points out that lead poisoning is often automatically treated with potassium iodide. The daily doses vary between 1 and 3 Gm. The author observed a number of patients with lead poisoning in whom more or less severe symptoms of hyperthyroidism developed. Nearly all were patients who for longer periods had been treated with potassium iodide. Symptoms such as profuse sweating emaciation nervousness and mild tremor were ascribed by the patients and also frequently by their physicians to the lead poisoning. However, since these symptoms were observed only in the cases of lead poisoning in which iodine therapy had been used and since in the early cases they had a tendency to disappear after the medication with potassium iodide was discontinued, it cannot be doubted that they were caused by the iodine. In this connection the author stresses the iodine sensitivity of the population of Vienna and of the Alpine regions in general. He describes the clinical histories of five patients and points out that younger persons seem to be in greater danger of developing iodine hyperthyroidism but that older persons also develop it occasionally after having tolerated it for a while. He shows that the potassium iodide therapy is best for the after-treatment of lead poisoning in the so-called state of latency for it aids in mobilizing and eliminating the lead deposits in the organism, whereas during the earlier stages it may even elicit colics, for it is now generally accepted that the lead which circulates in the blood and not the lead which is deposited in the body causes the symptoms. Moreover it is essential to keep the patient under strict supervision as long as he receives iodine therapy, and, as soon as tachycardia sweating or emaciation appears, it should be broken off.

Electrocardiographic Studies in Eclampsia—Eufinger and Molz made electrocardiographic studies on seventeen women with severe preeclampsia and on six women with eclampsia. They never detected electrocardiographic evidence of a direct cardiac impairment by the eclampsia. In six cases, or 26 per cent, the electrocardiographic aspects indicated a predominance

of the left side of the heart. Electrocardiographic control tests on eighty pregnant women without eclampsia disclosed this picture in only two cases (2.5 per cent). The authors designate as a predominance of the left side of the heart that condition in which the chief wave of the initial complex is directed upward in the first lead and downward in the third lead. The authors conclude that as the result of the increase in the peripheral resistances in preeclamptic and eclamptic women the left ventricle has a tendency to hypertrophy in order to be able to meet the increased requirements. They emphasize once more that they never observed evidence of a direct impairment of the heart.

Androgenic Substance in Female at End of Pregnancy

—Goecke reports investigations on the occurrence and behavior of androgenic substance ('testis hormone') in the female organism at the end of pregnancy. He detected androgen in 71 per cent of the placentas of female fetuses whereas its demonstration was never possible in placentas of male fetuses. These observations were corroborated by studies on the placentas of binovular twins of different sexes in that only the placentas of girls contained androgen. The absence of androgen from the placentas of boys is thought to be due to the fact that the hormone is utilized during the intra uterine life for the structure of the male fetus. It was impossible to demonstrate androgenic substance in the tissue of cystic mole but, since the urine of women with cystic mole contains large amounts of androgen, the assumption seems justified that there is no definite relationship between the quantity of androgen in the placenta and the amount that is excreted in the urine. The amniotic fluid contained only small traces of androgenic substance, regardless of whether the fetus was male or female. Androgen was found in the urine of women during the later stages of pregnancy when a boy was born later, not when a girl was born. Thus the elimination of androgen in the urine is the reverse of the androgenic content of the placenta. The author gives the following explanation. The placenta of a male fetus produces considerable amounts of androgenic substance but because of greater requirements of the male fetus it quickly passes into the blood stream, so that it is eliminated in the urine but cannot be detected at the site of production, the placenta of a female fetus, however, stores androgen so that it is demonstrable in the placenta but not in the urine. He suggests that the behavior of androgenic substance in the urine at the end of pregnancy permits, with some degree of reliability, a forecast of the sex of the fetus.

Clinical Use of Great Toe Phenomenon—Hammerschlag

shows that cerebral edema may develop in the course of a generalized stasis of cardiac decompensation in severe anemias and cachexias, in vasoneurotic conditions in severe infections and intoxications, and in diseases of the brain such as hemorrhages, tumors and inflammations. The edema may not involve the entire brain but affect only some portions. The clinical manifestations of cerebral edema differ. In the severe cases the neurologic symptoms although varied, permit a diagnosis; in the milder cases the diagnosis is often difficult. However, Edelmann's great toe phenomenon is pathognomonic for cerebral edema. The author searched for it in a large number of patients with chiefly internal disorders, in most of whom neuro-

logic complications were not expected. He gives a summary report of his observations on 100 cases in which he found the symptom positive. He elicits the reflex as follows. The patient lies flat, the examiner holds down the knee with the left hand, grasps the calf with the right hand and then bends the leg at the hip joint. In case of a positive reflex, there is dorsal flexion of the great toe. Occasionally it appears at a bending of only 45 degrees, but sometimes the leg has to be bent back beyond the vertical position. Occasionally there results a crossed reflex (toe of the other foot). The author refutes the objection that Edelmann's great toe reflex is identical with Babinski's reflex (indicative of a lesion of the pyramidal tract) and shows that it actually indicates cerebral or meningeal edema and not pyramidal lesions. Of the 100 patients in whom the sign was positive, sixty-three had cardiovascular disorders, fifteen had infectious diseases (influenza, pneumonia and so on) or severe intoxications (carbon monoxide, pancreatitis and others), twelve had disorders of the nervous system, such as meningitis, encephalomyelitis, epilepsy, cerebral hemorrhage and cerebrospinal syphilis, four had hematopoietic disorders and six had a severe cachexia. The author concludes that the sign helps in the early recognition of cerebral edemas of various origins.

*Symptomatology of Rheumatic Carditis. Ya. G. Ettinger and V. E. Nezhlin—p. 192
*Morbidity of Acute Rheumatism. M. D. Kuznetsov—p. 210

Rheumatic Carditis—Ettinger and Nezhlin state that clinical signs and electrocardiographic studies demonstrate the existence of myocardial lesions in the great majority of cases of acute rheumatism. Lesions of the endocardium are demonstrable by reconstruction of the history in cases in which definite symptoms of valvular lesions appear sometime after the attack. Diagnosis of endocarditis during the acute attack can be made only on the early appearance of a diastolic murmur at the base of the aorta. Cardiac alterations developing in the course of an acute attack of rheumatic fever are frequently of a reversible character, disappearing with the recovery from joint involvement. Rheumatic carditis uncomplicated by valvular lesions is frequently accompanied by a marked disturbance of the rhythm, without manifestations of cardiac insufficiency. Exacerbation of the rheumatic carditis with or without involvement of the joints is accompanied in many cases by signs of cardiac decompensation or by aggravation of the existing insufficiency. Acute exacerbation of the rheumatic carditis with signs of cardiac insufficiency is in many cases erroneously diagnosed in the absence of joint involvement as ordinary decompensation. Exacerbation of carditis may be observed in the course of the entire evolution of the rheumatic process up to the death of the patient from cardiac failure. Aschoff's nodes may be found in the myocardium of about one half of the patients dying from rheumatic cardiopathy. Exacerbations during the period of compensation of a rheumatic heart frequently present a polyarthritic syndrome. Manifestations of joint involvement appear less frequently with the later development of cardiac decompensation leading to a fatal issue.

Morbidity of Acute Rheumatism—The incidence of acute articular rheumatism, according to Kuznetsov, is 3.2 per cent of all internal diseases. The incidence is subject to seasonal variation, which attains its maximum during the winter and spring months and its minimum during the summer and autumn months. Among the grown up population the disease occurs with greatest frequency between the ages of 16 and 40. The history in cases of acute rheumatism reveals earlier infections, such as scarlet fever or pneumonia, in 69.2 per cent. According to the author they create conditions favorable to sensitization of the organism. Sore throats are the commonest recent ailments. A clinically demonstrable heart lesion is present in 43.2 per cent of the cases of rheumatic polyarthritis, with the most frequent localization of the process in the mitral valves. Cases of rheumatic polyarthritis can be separated into two

types those without signs of involvement of the heart and those with involvement of the heart. Recurrence of attacks takes place in 54.3 per cent of the cases, most frequently in those in which there is definite involvement of the heart.

*Sensitivity Produced by Neoarsphenamine During Antisyphilitic Treatment. P. J. Van Putte—p. 2123

Sensitivity Produced by Neoarsphenamine.—Van Putte found that 10 per cent of the syphilitic patients treated at the Latavia Hospital during 1933 and 1934 suffered from sensitivity to neoarsphenamine and that the third injection offers the greatest possibilities for anaphylactic disturbances. The fatal accidents and the grave disorders have always occurred in cases in which 0.3 or 0.45 Gm. was given at the first injection and 0.6 Gm. at the second or third. By administering systematically 0.075 Gm., 0.15 Gm., 0.3 Gm. and 0.45 Gm. for the first four injections at four day intervals he has not had any fatalities among 3,000 patients, and the treatment from then on was continued with injections of 0.6 Gm. every five or six days until 5 Gm. of the drug was given. An injection of an oily suspension of bismuth hydroxide, containing 0.1 Gm. of metallic bismuth, was allowed regularly between neoarsphenamine injections. A treatment lasted seven or eight weeks. In serum negative primary syphilis he has given two of these treatments with an interval of rest of one month and in serum positive primary syphilis, in primary and secondary syphilis and in secondary syphilis three of the treatments with an interval of rest of six weeks between the second and third. All patients have been clinically cured and the Wassermann reaction of the blood and spinal fluid have remained negative. The author takes exception to Hoffmann's "maximal cure," in which from 7 to 8 Gm. of neoarsphenamine is given in six weeks, and points out how impossible it is, under the circumstances, to take Hoffmann's advice to proceed with prudent increase in dosage on account of lack of time.

Investigations as to Whether Blood Sedimentation Rate Measured by Westergren's Apparatus Is Dependent on Intake of Food. A. Eldahl—p. 419

Dry Pleurisy.—Twenty-eight cases are reported in which dry pleurisy was the main diagnosis. Tuberculous etiology seemed certain in seven cases and highly probable in nine. After-examination shows that fifteen patients have continued well for from two to nineteen years (ten for more than five years), tuberculosis has been established in more than 25 per cent of the material. Strandgaard says that the dominant feature in the disorder is the vague and indefinite nature of both subjective and objective symptoms. Roentgen examination often reveals latent changes in the lungs or small exudates and is called for in every case.

Mediastinal Tumors Treated Surgically.—Bull previously reported two cases of dermoid cyst in the anterior mediastinum in 1929 and one of fibromyxanthoma in 1931 in

which operation was performed, the patients are living and well. In the first case now described, of microscopic diagnosis of myxosarcoma, there was sudden onset with violent pain in the left side of the chest and the left arm and hemithorax. On operation in 1932 a soft tumor, the size of an orange, was excised from the posterior mediastinum, the patient continues well. In the second case, of bronchogenic cyst there were sudden laryngospasms repeated almost daily for two months. Transpleural extirpation of the cyst was done. Death occurred from mediastinitis. In the third instance, a solid tumor microscopically diagnosed as a fibroblastic tumor of moderate malignancy was excised from the anterior mediastinum. Thoracoplasty was performed and complete healing resulted. Nine months later hemoptysis occurred and a cavity the size of a walnut appeared under the right clavicle, the operative intervention is believed to have revived an old disorder in the top of the lung. In the last case, atypical sarcoma in the anterior mediastinum, probably from a neurofibroma there had been paroxysmal coughing with vomiting sense of oppression and pain radiating to the neck. Roentgen examination showed a tumor the size of an egg in the upper left side of the chest four months later, in January 1935 the tumor had doubled in size. Preceded by artificial pneumothorax transpleural extirpation was easily accomplished. The tumor situated above the heart was solid and weighed 184 Gm. In December 1935 the patient was well and had been pregnant for five months. The author emphasizes that mediastinal tumors often set in suddenly and with rather unusual symptoms, as in five of his seven cases and that it may be difficult to determine before operation whether the tumor is malignant or benign. He says that roentgenography in several planes is necessary for localization of the tumor before operation. Artificial pneumothorax aids in making the roentgenogram clearer, and thoracoscopy is probably the best means for localizing the tumor and at the same time affording an idea of its nature. Rectal ether-oil narcosis may be advantageous in these interventions.

*Changes in Electrocardiogram in Orthostatic Circulatory Disturbances. S. Åkesson—p. 383

Orthopedic Prophylaxis Outside of Special Orthopedics. P. Haglund—p. 501

Electrocardiogram in Orthostatic Circulatory Disturbances.—Åkesson made anthropometric examinations of 200 healthy men, aged 21, in military service, and by means of the index $\frac{\text{chest width} \times \text{chest depth}}{\text{body length}^2}$, or $\frac{ab}{P}$, selected the forty of most asthenic and the forty of least asthenic bodily habit for closer examination of electrocardiograms and the blood pressure taken in the standing and in the reclining position. Electrocardiograms recorded in the standing position showed an inversion of T_1 or T_2 in twenty-four cases, or 31 per cent and of T_3 in three, or 4 per cent. Electrocardiographic examination of forty-five patients with clinical diagnosis of arterial anemia made in the standing position showed an inversion of T_2 or T_3 in thirty-one, or 69 per cent, and of T_1 in twenty, or 44 per cent. The author states that the more marked the degree of asthenia according to the index $\frac{ab}{P}$, the greater the decrease in the height of T_2 in the standing position, and also that there is a relation between another index of bodily habit, $\frac{\text{weight}}{\text{body length}^3}$, or $\frac{v}{P}$, and the decrease in the height of T_2 in the standing position. The greater the pulse frequency of the standing person the greater is the decrease in the height of T_2 , the greater the rise in his pulse frequency, the greater is the decrease in the height of T_2 , and the greater the fall of his systolic pressure and of his blood pressure the greater is probably the decrease in the height of T_2 . In two cases of arterial anemia examined in the pool, the electrocardiographic symptoms disappeared after the orthostatic pressure had been equalized by allowing the water to rise to the height of the heart. In three of the seven persons in the entire material who fainted during registration in the standing position, the deflections of the electrocardiogram corresponded to those described by other authors in cases of marked excitation of the vagus.

THE PROBLEM OF CANCER OF THE PANCREAS

CHAIRMAN'S ADDRESS

HOWARD M. CLUTE, M.D.
BOSTON

Recent surgical literature has contained an increasing number of contributions relating to the surgery of the noninflammatory lesions of the pancreas. The discovery that tumors of the islands of Langerhans could cause hyperinsulinism was followed by reports of the successful surgical removal of these small tumors from the pancreas by Roscoe Graham,¹ Judd² and Whipple and his associates,³ and subtotal pancreatectomy for hyperinsulinism has recently been reported by Evarts Graham⁴ and McCaughan.⁵ New interest has been directed to the radical surgery of the pancreas by reports of successful removal of malignant tumors involving the papilla of Vater by Judd⁶ Walters,⁷ Potter,⁸ Hunt,⁹ Whipple and his associates¹⁰ and by the occasional reports of the radical removal of malignant growths involving the body or tail of the pancreas, which likewise have appeared in the literature.¹⁰

It would appear most opportune at this time, therefore, to present to this section a brief review from the literature and from personal experience of the symptomatology, and especially the early symptomatology, of cancer of the pancreas, and to discuss the problems that are involved in the surgical attack on this lesion. I have not had the opportunity of carrying out the procedures to be considered save in the autopsy room. It

is hoped however that, by directing the attention of this group of surgeons to the problem of cancer of the pancreas, further progress in the management of this disease will be made.

INCIDENCE

Cancer of the pancreas is by no means a rare disease. Bigelow and Lombard¹¹ found that 4.8 per cent of the cancer deaths in Massachusetts hospitals in 1928 to 1930 were due to cancer of the pancreas. Hoffman,¹² in a statistical study of cancer of the pancreas, says it is safe to assume that 3 per cent of all cancer deaths arise from cancer of the pancreas and total 4,000 a year in the United States.

PATHOLOGY

The malignant process in the pancreas may originate in the parenchyma of the gland, in the pancreatic ducts, or rarely in the islands of Langerhans. The most frequent type of tumor is adenocarcinoma, although scirrhous forms are not infrequent. Most pancreatic cancers are primary in the pancreas, but a very few are primary in the biliary tract or duodenum and invade the pancreas secondarily.

The tumor is most frequently located in the head of the gland. In a series of 678 cases collected from the literature by Leven,¹⁴ 56.3 per cent were in the head of the gland and 30.7 per cent were diffusely spread through the pancreas. Only 6.6 per cent were limited to the tail of the pancreas and 6.3 per cent to the body, 8.7 per cent are in the head or are diffuse and so are least subject to surgical attack.

METASTASES

Pancreatic cancer may metastasize by (1) direct extension into contiguous organs, (2) growth through the lymphatics or (3) invasion through the adjacent blood vessels. To the surgeon the rapidity with which these tumors metastasize is most important, and in general it may be said that most pancreatic cancers form metastases within a few months after they are discovered. In one personal experience with a small tumor in the head of the pancreas extensive metastases to the liver were present five months after the original exploration had shown no evidence of any extension of the growth. All are familiar however, with other exceptional cases in which the appearance of metastases has been delayed for months or years. Thus in my experience, one man lived four and a half years after cholecystogastrostomy before evidence of metastasis was noted.

Read before the Section on Surgery General and Abdominal at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City Mo., May 14, 1936.

Direct extension of the malignant process into contiguous viscera occurs in the later stages of the disease, and metastases have been noted in the duodenum, the stomach, the colon, the kidneys and ureters, the spleen, the adrenals and the general peritoneal cavity.

It is probable that most cancers of the pancreas first metastasize into the regional lymph nodes. As may be seen from the artist's drawing, innumerable lymph nodes lie in close proximity to the head of the gland and beneath the body and tail (figs 1 and 2). These are early and often involved in the malignant process.

Secondary growths are most frequently found in the liver, and it is probable that these arise as a result of invasion of the veins, emptying into the portal system. Metastases to the lungs and pleura have been frequently reported. Generalized metastases in pancreatic malignancy are rare.

PATHOLOGIC PHYSIOLOGY

As a tumor in the pancreas grows it may produce changes in physiologic function by obstructing the common bile duct, by obstructing the pancreatic ducts by influencing the activity of the islands of Langerhans, or by invading the adjacent viscera. Obstructive jaundice and interference with liver function are very common in cancer of the pancreas. This would be expected since 87 per cent of the tumors sooner or later involve the head of the gland and so can encroach on the common bile duct. Difficulties from a loss of pancreatic secretion are not common, owing, no doubt, to the ability of intestinal secretions to manage, in its

Fig 1—Head of the pancreas turned back to show the numerous lymph nodes to which metastases may spread. The relations of the superior mesenteric vessels, portal vein and common bile duct to the pancreas and duodenum are clearly revealed.

absence, a large part of the digestive functions of the pancreatic secretion. Hyperinsulinism from excess production of insulin by a tumor of an island of Langerhans is rare. Duodenal obstruction and gastrointestinal bleeding from invasion of the gastro-intestinal canal by pancreatic cancers is a frequent late occurrence in the course of malignant growths of the pancreas.

Diabetes mellitus is rare, since the islands of Langerhans often persist in spite of extensive pancreatic cancer.¹⁵ Eusterman¹⁶ found that glycosuria was conspicuous by its infrequency. Friedenwald¹⁷ found only one case of permanent glycosuria and five of transient glycosuria in thirty-seven cases. Hick and Mortimer,¹⁸ however, noted that eight of their fifty cases presented diabetes.

Fig 2—Tail of pancreas turned back. Note the pancreatic branches from the splenic artery and vein that have been ligated. The numerous lymphatic glands behind the pancreas are seen.

SYMPTOMS

Progress in the treatment of pancreatic cancer is largely dependent on the early diagnosis of this lesion before it has become extensive in its growth and before metastases have occurred. It is highly important, then, that the earliest symptoms which may point to pancreatic malignancy shall be listed and reviewed so that the goal of early diagnosis may be more frequently reached.

It is doubtless true that the first step in the early diagnosis of cancer of the pancreas is the recognition by physicians of the significance of rather vague digestive symptoms in male patients in middle life. It is probably true that sufficient data could readily be obtained in many of these cases which would at least justify a surgical exploration if the possibility of cancer of the pancreas was more often considered and investigated.

All physicians are familiar with those cases of cancer of the pancreas which show as their typical symptoms painless jaundice, distended gallbladder, cachexia and weight loss, as first described by Bard and Pic.¹⁹ One will rarely see a patient presenting these appearances, however, in whom there is not a history of several

weeks of epigastric discomfort and distress, indigestion, flatulence and often pain preceding the jaundice. Twice I have had jaundice develop in patients while under hospital observation for ill defined digestive disturbances. In each instance cancer of the pancreas with a widely dilated common duct was found at operation a few days after the onset of the jaundice. It would appear that the typical picture described by Bard and Pic¹⁰ is the picture of late pancreatic cancer which has progressed sufficiently to obstruct the common bile duct.

The early symptoms suggestive of cancer in the pancreas are not distinctive and for this very reason the diagnosis of pancreatic cancer should be considered when careful examination fails to reveal a definite lesion in the stomach, duodenum, colon or gallbladder to account for the patient's new digestive trouble.

Most writers²⁰ agree that epigastric pain is the commonest early symptom of pancreatic cancer. This is usually dull, boring and penetrating in character. Occasionally the pain is colic-like and when this occurs may well be due to the association of gallbladder stones with the pancreatic cancer. Accompanying the pain very often are digestive distress and epigastric fulness, and in many instances abdominal distention.

A very large and usually a very rapid weight loss is the second most common early symptom of this disease. In many cases the loss of weight is more than 50 pounds (23 Kg) and it generally occurs in a very short time. Such large and rapid weight loss in a man at middle life should always be highly suggestive of pancreatic cancer, particularly if no other adequate cause can be found to account for it.

The length of time from the first evidences of pancreatic cancer to the appearance of jaundice varies, of course, with the location of the tumor in the pancreas and its relation to the common duct. Occasionally the first symptom that can be elicited from the patient is the appearance of jaundice. This is unusual and in many cases weeks or months of digestive trouble go by before jaundice is noted. The longer this interval, the more probable it is that the tumor did not arise in the head of the gland. In at least 10 per cent of cases no jaundice ever appears in the course of the disease.

When the tumor arises in the body or tail of the pancreas, jaundice either is long delayed or is never encountered. Here attacks of severe pain due to the pressure of the tumor on the vessels and nerves behind the pancreas are at times encountered. Chauffard²¹ refers to a "syndrome pancreatico-solaire" seen in these cases, to be distinguished from the "syndrome pancreatico-biliaire" of Bard and Pic¹⁰ which is present when the tumor lies in the head of the pancreas. The pain in cancer of the body or tail of the pancreas is usually referred to the back on either side and across the epigastrium. It is occasionally relieved if the patient leans forward and so removes the pressure of the tumor from the retroperitoneal structures.

PHYSICAL SIGNS

In many instances the very absence of physical signs on examination must be, in itself, suggestive of pancreatic cancer. In the advanced case, however, of cancer in the head of the gland, the jaundice is persistent with no remissions. The gallbladder is dilated

and can be felt in more than half of the cases. A sausage shaped epigastric tumor may at times be palpated when the lesion involves the body or tail of the gland. Eusterman¹⁰ recommends the intravenous administration of from 3 to 5 grains (0.2 to 0.3 Gm) of sodium amytal in patients suspected of pancreatic cancer. With the muscular relaxation thus obtained, a tumor may at times be palpated in the body or tail of the gland.

In every patient thorough gastro-intestinal x-ray study should be done to rule out lesions in the stomach, duodenum, gallbladder or colon. By these x-ray studies a wide sweep of the duodenum around the head of the pancreas may be noted, or the greater curvature of the stomach may be encroached on by an obviously extra-gastric lesion. Engel and Lysholm²² have attempted to obtain special films of the pancreatic area by first giving the patient an effervescent powder to fill his stomach with gas. They then take lateral and anteroposterior

Fig 3—Starting the surgical approach to the pancreas by dividing the gastrocolic omentum. Great care must be taken to avoid injury to the middle colic artery.

plates and believe they can outline pancreatic tumors in certain cases. Further progress in x-ray technic will no doubt be made to aid in earlier diagnosis of these cases.

Duodenal tube drainage of the region of the ampulla will very often show an absence of bile and may show blood. Such changes are very suggestive of pancreatic cancer. If the tumor of the pancreas is in the body or tail, however, the duodenal tube may reveal little or nothing of diagnostic help. Blood may be persistently present in the stools in those cases in which the tumor has invaded the duodenum or stomach.

In a few cases traces of sugar will be found in the urine, but true diabetes in cancer of the pancreas is not as common as has been thought.

Tests of urine, stools and blood for evidences of faulty pancreatic function have not as yet proved of practical value in diagnosing pancreatic cancer, no doubt because of the ability of relatively small portions of the gland to carry on its functions.

DIAGNOSIS

The diagnosis of the well advanced case of pancreatic cancer with weight loss, pain, progressive jaundice and a palpable mass in the right upper portion of the abdomen is readily made. Stones in the common duct, however, may give these identical symptoms and in certain cases cannot by any present methods be certainly differentiated from cancer of the pancreas. This fact cannot be overemphasized, since it is such a basic reason for urging the surgical exploration of patients who appear to have hopeless pancreatic cancer.

The diagnosis of early cases of pancreatic cancer, however, is dependent, first, on the clinician's recognizing the possibilities of the lesion and consciously attempting to prove or disprove its presence. I am convinced that measures to attack pancreatic cancer will be limited until either we think of its possibility more frequently or develop new diagnostic measures for its earlier detection.

The occurrence in a man at middle life of digestive disturbances, epigastric fullness and discomfort, pain and weight loss warrant a thorough study by all the means available. If no positive diagnosis is revealed

Fig. 4—Approach to the pancreas may be made by dividing the gastrohepatic omentum and displacing the stomach downward. Exposure of the tail of the gland is less complete by this method.

by examination and gastro-intestinal studies, the possibility of pancreatic cancer must be considered at once. Auscultation of the abdomen, palpation for a deep tumor, under anesthesia if need be, and repeated studies for the possibility of an increase in the bilirubin of the blood may reveal sufficient further evidence to warrant exploration of the upper part of the abdomen. In many instances all available data will be too indecisive to permit a positive diagnosis but will nevertheless be sufficiently suggestive to warrant exploration of the abdomen.

TREATMENT

In cancer of the pancreas, in common with cancer elsewhere in the body, there are three possible measures for treatment, which may be used singly or in combination. These are high voltage roentgen therapy, radium treatment and surgical excision.

High voltage roentgen therapy for cancer of the pancreas has received but little attention from the profession, and the literature contains few references to its use in this condition. Dr. G. E. Richards²³ of Toronto treated three cases in 1920 and published his results

in 1922. Two of his three patients showed marked improvement for a time, but all three eventually died. Dr. Richards has not continued the use of high voltage roentgen therapy in cancer of the pancreas. Dr. H. Flecker and Dr. Gordon Cameron²⁴ in Australia noted his work, however, and in 1925 reported several cases of pancreatic cancer treated in the course of some experimental work on the blood sugar after high voltage roentgen therapy of the pancreas. They reported marked improvement in some of their cases for a time, but their paper lacks detailed case reports. Von Redwitz²⁵ found no value in high voltage roentgen therapy for cancer of the pancreas. Leven²⁶ reported in 1933 the treatment of four cases by high voltage roentgen therapy. Each of his patients had had a cholecystenterostomy. All four died within a short time and no improvement was noted from roentgen therapy.

Fisher, Groot and Bachem²⁷ and also Ivy, McCarthy and Orndoff²⁸ have produced fibrosis, atrophy and even diabetes experimentally by intensive roentgen therapy over the pancreas. All reported the marked ability of the pancreas to regenerate following this treatment.

During my service in the Laker Clinic I had the opportunity of following five patients with apparent cancer of the pancreas who were given roentgen therapy at my suggestion. Three of these cases seemed to show some improvement following this therapy, and two were apparently not affected by it. Since equal improvement has been seen in other patients who had not had roentgen therapy, it is not possible to draw any deduction from this experience. Certainly high voltage roentgen therapy would appear to be the least valuable type of therapy available in cancer of the pancreas. On the other hand, further refinement in apparatus and technique may render it far more useful and x-rays should not be lost sight of as a possible therapeutic agent in malignant conditions of the pancreas.

Very little clinical work has been reported on the use of radium in malignant disease of the pancreas, yet it would seem that this might be a logical approach to the treatment of this lesion. Handley²⁹ of London has treated seven cases of pancreatic cancer, all in the head of the gland, with radium element. All seven patients had biliary intestinal anastomoses made at the time of the radium application, and four patients died postoperatively. One, however, lived fourteen years, one twenty-six months, and one was still alive ten months after the operation. Handley reports no biopsies in these cases, however, so that the certainty of the diagnosis is rather unsettled. Most important, however, is the fact that Handley demonstrates that radium may be safely applied to cancer of the pancreas in human patients.

From the experimental point of view, Leven³⁰ found that radon in gold seeds would produce a marked fibrosis and atrophy of the pancreas in dogs. He found that the gland regenerated rapidly after irradiation, and he believes that radon may be safely implanted in the

human pancreas. In a later paper he states that he placed gold implants of radon in the substance of a small tumor in the head of the pancreas. The patient died of hemorrhage into the gastro-intestinal tract.

Very possibly a two-stage operation, in which a biliary intestinal anastomosis was done at the first stage and radium implanted at the second, would be desirable. Only a short interval of two or three weeks should intervene between stages. With this procedure, the jaundice could be overcome by the first operation and definite plans made for the amount of radium to be used at the second operation, in view of the location and size of the tumor. It would appear that the problem of radium therapy in cancer of the pancreas should receive further study.

SURGICAL TREATMENT

It is now becoming more generally accepted that the seriously jaundiced patient who apparently has cancer of the pancreas should have a surgical exploration for two purposes: (1) to make as certain as possible that the jaundice is due to cancer of the pancreas and not to common duct stones or pancreatitis, and (2) to consider anastomosis of the gallbladder or common duct to the stomach or intestine for the purpose of relieving the jaundice.

It must be recognized however, that simple exploration in cancer of the pancreas carries a definite mortality with it and that the average length of life after exploration is less than with no operative procedure. In my experience the average length of life in cancer of the pancreas unoperated on is 7.2 months after the first diagnosis is made, and after simple exploration it is but three months. Exploration, therefore, is not advisable in the far advanced cases and should not be done unless one has a reasonable certainty that at least a biliary intestinal anastomosis can safely be made.

Biliary intestinal anastomoses also carry a heavy immediate mortality, which varies in different clinics, doubtless because of a difference in the selection of cases. These patients, furthermore, are prone to develop later difficulties from infection of the biliary tract from the anastomosis. These factors, however, should not condemn the procedure. The postoperative improvement which these jaundiced patients obtain from a successful short circuiting operation is often remarkable, and the majority are at least temporarily relieved of their jaundice. There are occasional cases in every one's experience of patients who live several years after this procedure. The average duration of life after this operation is but seven months, however, even when the unusually long survivors are included.³⁰

In all these operative procedures for pancreatic cancer it is evident that the surgery is undertaken only at the terminal stage of the disease and is complicated by the presence of obstructive jaundice, which is usually of long duration. Can we not hope to develop diagnostic methods and clinical acumen sufficiently keen to permit us to approach malignant lesions of the pancreas at earlier stages, and with the plan of undertaking radical removal of the malignant process?

The literature of cancer of the pancreas is filled with statements to the effect that, because of its deep situation and the difficult approach, radical removal of the pancreas is either impossible or at least most unwise. Most studies of pancreatic malignancy have come from medical men and pathologists. Surgeons until recently

have but rarely discussed radical pancreatic operations save in the light of palliative measures for the relief of jaundice.

Finney^{10a} in 1910 successfully removed a tumor of the body of the pancreas and found reports of sixteen other cases of removal of pancreatic cancers in the literature with a 50 per cent mortality. In 1928^{10b} he reported the successful resection of part of the pancreas for hypoglycemia. At this time he stated his belief that in the eighteen years since his previous report radical surgery of the pancreas had advanced but little.

In 1907 Desjardins³¹ and in 1908 Sauve³² suggested very radical procedures for the removal of malignant tumors of the head of the pancreas. These operations included a biliary intestinal anastomosis, a resection of the head of the pancreas and the duodenum, a reuniting of intestinal continuity, and finally the insertion of the pancreas or its duct into the intestine. The division of these steps into two operations was proposed. These procedures were attempted only a few

Fig. 5.—The parietal peritoneum over the pancreas has been divided and the tail lifted with a double hook. Each branch of the splenic artery and vein is dissected and divided as the removal of the tissue continues.

times and were generally considered as far too radical to be undertaken by conscientious surgeons.

Recent reports of successful resections of the head of the pancreas have been made by Whipple, Parsons and Mullins,³ who followed these fundamental procedures proposed by Desjardins and Sauve with one notable change. They ligated the pancreatic ducts and made no attempt to provide for the escape of the external secretion of the pancreas. MacCallum³³ had done this with animals in 1909 in the laboratory and found that this resulted in some atrophy of the pancreas but was by no means incompatible with life. By this procedure the formidable procedures of Desjardins and Sauve were made more practical and were more readily applied. It would appear that the way is now clearly opened by this work of Whipple for wider study of the problem of resection of the head of the pancreas.

30 Judd and Parker, C. Coller, F. A. and Winfield, J. M. Evaluation of Palliative Operation for Cancer of the Pancreas. *Am. J. Surg.* 25: 64-69 (July) 1934.

Less complicated problems are involved in resections of the body or tail of the pancreas for cancer, since jaundice is absent and since neither biliary nor gastrointestinal anastomoses are necessary.

The incision in the abdominal wall to approach the body or tail of the pancreas has commonly been a longitudinal one in the left rectus (fig 3). This may

Fig 6—The dissection has been carried over to the superior mesenteric vessels. The cut end of the pancreas has been folded over with catgut sutures.

be enlarged by an additional transverse incision to the left, if need be. Whipple³⁴ finds that a transverse incision across both rectus muscles above the umbilicus gives the best exposure.

Tumors of the body or tail of the pancreas may be exposed surgically through the gastrohepatic omentum, the gastrocolic omentum or the transverse mesocolon. The latter route is probably of little value, and its practical use I have not found recorded in the literature. Finney,¹⁰ Judd⁶ and Gordon-Taylor¹⁰ all approached the pancreas through the gastrohepatic omentum (fig 4). Judd remarks that exposure may be increased if need be by going through the gastrocolic omentum. Most recent radical surgery on the pancreas, however, has been through the gastrocolic omentum. Thus Roscoe Graham,¹ Evarts Graham,⁴ Holman,³⁵ Cottalorda,³⁶ McCaughan⁵ and Whipple³⁴ have all found this the most satisfactory route for exposing the gland.

The vessels in the gastrocolic omentum are divided along the greater curvature of the stomach (fig 3). Care is taken to avoid injury to the middle colic artery, which should be well out of the way unless adhesions in the lesser peritoneal sac obscure it. With properly placed packs of wet gauze, the stomach is now retracted

upward and the colon downward, and the entire body and tail of the pancreas are brought into view. McCaughan⁵ recommends elevation of the patient's back by a suitable back rest to bring the pancreas into better position. This would seem a point of definite advantage, especially in stout patients.

With adequate exposure the removal of the tumor of the pancreas may now be undertaken. Dissection is best started at the tail of the pancreas by incision of the peritoneal layer overlying the gland, starting gently to elevate it from its bed (fig 5). The splenic artery and vein lie in close relation to the pancreas and form the chief complication to its easy dissection. Holman³⁵ believed he would ligate them and do a splenectomy if any difficulty was encountered in dissecting them. McCaughan⁵ retracts the vessels early in the dissection and lifts them with a tape to facilitate the catching of their numerous pancreatic branches. Gordon-Taylor,¹⁰ however, states that in removing a large tumor of the body of the pancreas he ligated the splenic artery and vein and noted no difficulty after operation that was related to interference with the blood supply of the spleen. This procedure would appear to be unwise for routine use.

As the dissection is continued from left to right, the superior mesenteric vessels are soon encountered (figs 1 and 2). Here great care, precision and gentleness must prevail in order that they may be left intact. Gordon-Taylor¹⁰ found the tumor in his case so adherent to the portal vein that he removed part of its wall and closed it by suture over an intestinal clamp that he placed longitudinally on it.

Control of bleeding must be largely by hemostat and ligature, though veins may well be closed with a running suture (fig 6). Division of the body of the pancreas itself is best done by making a wedge-shaped excision,

Fig 7—The incision in the gastrocolic omentum has been closed about a cigaret drain that leads to the cut end of the pancreas.

which can then be closed by interrupted or continuous sutures. McCaughan⁵ has found it desirable to place a rubber covered right angle clamp on the gland before cutting it off in order to control the bleeding. Von Haberer employs the electric cautery in excising portions of the pancreas.

An escape of pancreatic fluid is so prone to occur after pancreatectomy that all writers agree that a drain should be left in place down to the cut surface of the organ (fig 7). Drainage of pancreatic secretion may continue from a few days to several months and will occasionally require much attention to prevent digestion of the wound surfaces.

Surprisingly few reports are to be found in the literature of successful removal of malignant tumors of the body or tail of the pancreas in the hundred years since Mondiere³⁷ first described cancer of the pancreas. Recent interest in the surgical treatment of pancreatic tumors has been so stimulated by the results obtained by resection of the pancreas or of islet tumors for hyperinsulinism that we may surely anticipate an increase in the number of pancreatic cancers attacked surgically. Wider study of the early symptoms of pancreatic cancer will give increasing opportunity for the application of surgical and radiologic measures to the pancreas. The pancreas is no longer in the realm of the surgically "untouchables" and can readily be approached by surgeons well trained in the management of serious abdominal diseases.

CORONARY ARTERY DISEASE IN WOMEN

HYMAN LEVY, M.D.
AND
ERNST P. BOAS, M.D.
NEW YORK

In women, especially those under the age of 50, coronary artery disease is unusual in the absence of diabetes or hypertension. Yet precordial pain simulating angina pectoris is a very common symptom. Although experienced clinicians have been aware of this fact for years, it is overlooked again and again in daily practice and many mistaken diagnoses result.

During the past seven years in an office practice representing largely patients referred for cardiovascular diagnosis, we have seen 1,672 women, of whom 169, or 10.1 per cent, had coronary artery disease. In the same period we saw 2,135 men, of whom 1,059, or 49.6 per cent, had coronary artery disease. The frequency is 4.9 times as great in men as in women. Of the 169 cases in women 125, or 74 per cent, were associated with hypertension alone, twenty-five, or 14.8 per cent, with both diabetes and hypertension, and sixteen, or 3.5 per cent, with diabetes alone. In only thirteen cases, or 7.7 per cent, was there neither hypertension nor diabetes, and of these only five were in women under the age of 50. In many of the cases in the last group the diagnosis of coronary artery disease is open to some doubt. Fully 50 per cent of the male patients with coronary artery disease had neither hypertension nor diabetes. Approximately one third of all the female patients with hypertension seen by us have coronary artery disease.

Heberden¹ observed only three women in his series of 100 patients with angina pectoris, Forbes² saw eight

in eighty-eight, Osler³ one in forty, and Burwinkle⁴ seventeen in 117. More recent statistics also show a great preponderance of coronary disease in men. White⁵ found the ratio of incidence in men as compared to women to be 3 to 1. Gallavardin⁶ found a ratio of 4.7 to 1. In 1,431 consecutive necropsies showing coronary sclerosis studied by Willius, Smith and Sprague,⁷ men outnumbered women 3.2 to 1. Other observers have reported approximately the same figures.⁸

The validity of all such statistics depends on the criteria employed for the diagnosis of coronary artery disease, and in this respect some of the older literature in particular is open to question. We employed strict criteria for the diagnosis of coronary artery disease. The diagnosis of angina pectoris was made only if the history revealed a typical Heberden's syndrome, that is, substernal or left parasternal pressure or pain provoked by effort or excitement, compelling the patient to halt his activities. In many instances there was typical radiation to the left arm and aggravation of symptoms on exertion after meals or in cold or windy weather. Coronary sclerosis with myocardial fibrosis was diagnosed when, in addition to the classic history, there were electrocardiographic changes indicative of myocardial injury, such as deformation of the RT segment or the T wave or marked alteration of the QRS complex. Coronary thrombosis was diagnosed when there was a history of an attack of severe substernal pain, lasting one or more hours, accompanied by symptoms of shock, often with subsequent cardiac insufficiency, compelling rest in bed for a period of weeks following the attack. We excluded all cases of syphilitic aortitis, as well as all cases of aortic insufficiency of whatever origin.

The favoring influence of hypertension on the development of coronary artery disease in women has been noted by several authors. White⁵ remarks that "many of the women with angina pectoris have hypertension, which may be of enough importance in increasing cardiovascular strain to be in part responsible." Eppinger and Levine⁹ write "One should therefore hesitate to make the diagnosis of angina pectoris unassociated with coronary thrombosis for any woman with a low blood pressure, especially for those under 50 years of age." Mackenzie¹⁰ writes "When therefore we find a woman under 50 with no gross disease of the heart or when we can exclude arterial degeneration, we may fairly assume that the anginal attacks are secondary, especially in women before and about the menopause." In Gallavardin's⁶ series only five of

sixty-six women with coronary artery disease had normal blood pressures and hearts that were not enlarged

Nor has the fact escaped attention that the presence of diabetes mellitus increases the incidence of coronary artery disease in women. Root and Graybiel¹¹ showed that the frequency of coronary artery disease in diabetic patients is almost the same in the two sexes. Contrasting this observation with the usual great excess of coronary artery disease among males they conclude that the diabetes is the cause of this "leveling influence." On the basis of necropsy studies Nathanson¹² reaches a similar conclusion. He finds that in diabetes the tendency to coronary arterial changes is almost as great in the female as in the male. This is true not only of the coronary arteries but even more so for the peripheral arteries. Cases of coronary thrombosis have been described in female diabetic patients under the age of 35.¹³

Ordinarily the diagnosis of coronary artery disease is simple, particularly when there are objective physical

It is the cases that simulate coronary artery disease which require more detailed discussion. This is most graphically done in the light of some illustrative cases.

REPORT OF CASES

M. S., a woman, aged 47, had had a cholecystectomy for gallstones without relief of the symptoms. In October 1925 when she was 37, she was greatly disturbed by some happening and a few hours later a squeezing choking pain developed high in the epigastrium which radiated up the sternum and down the left arm. The late Dr. M. H. Kahn saw her at this time. Her face and hands were white. The blood pressure was 136 systolic 94 diastolic. She was kept in bed for three weeks and had repeated mild pains in the upper part of the chest during this period. The electrocardiogram was negative. On admission to Mount Sinai Hospital in 1927 she complained of severe epigastric pain coming fifteen minutes after meals, radiating to the left and lasting from two to five hours. For half a year she had been having attacks of severe precordial pain radiating to the left arm and right shoulder. The pain was constant, and about twice a week she had attacks during which it became more severe, especially on exertion. Physical examination was negative, the blood pressure was 130 systolic, 90 diastolic, and the electrocardiogram was negative. Roentgenography revealed

or electrocardiographic signs of heart disease. In many cases, however, objective evidences are absent and the diagnosis must be made on the history alone. This too offers few difficulties in men, because the story of clamping substernal pain on exertion or excitement compelling the patient to arrest his activities, is so clear cut. At times relief of the seizure by glyceryl trinitrate further confirms the diagnosis. When the histories are colored with secondary, usually functional, symptoms the picture is more obscure, the primary symptoms stand out less clearly, and diagnosis may be difficult. This obtains particularly among women patients, in whom even in the presence of coronary artery disease the syndrome is often marked by vasomotor symptoms. The diagnosis of coronary artery disease often depends primarily on the evaluation of symptoms, and this at times is very difficult in women. Mistaken diagnoses of angina pectoris in women are due to a misinterpretation of symptoms and to ignorance of the rarity of coronary artery disease in women who have neither hypertension nor diabetes.

There is no need to elaborate the clinical picture of true coronary artery disease as it occurs in women, for it does not differ from the generally recognized form

some enlargement of the left ventricle. Roentgen study of the gastro-intestinal tract was negative.

We first saw her in 1932, when she complained that for a few weeks she had had episodes of sharp sticking pain to the left of the sternum, which radiated to the left shoulder and arm, brought on by exertion and excitement and accompanied by weakness and nausea. Physical examination and electrocardiography again were negative, fluoroscopy revealed moderate left ventricular enlargement, the blood pressure was 118 systolic, 80 diastolic. A year later she reported that she had been well for six months but that then the precordial pain had returned on walking, her chief complaint however, was epigastric and right hypochondriac pain. Again there was no change in the physical and electrocardiographic manifestations.

She was last seen in February 1936, more than ten years after the onset of the illness. She has much the same symptoms. While doing her housework she becomes dizzy and weak and experiences choking cramps over the entire chest. At times she can walk freely and at times she is compelled to rest after walking a block because of pressure in the lower part of the sternum. Frequently her body shakes and she has palpitation. She is nervous and feels as though "a machine were working in her body." Again physical examination is negative and the electrocardiogram unchanged.

The major attack at the age of 37, together with the present history, suggests coronary artery sclerosis and that she probably experienced a coronary thrombosis at the onset. However, the early age at onset, the persistence of severe symptoms for ten years without the development of any objective signs, and the varied

abdominal symptoms, as well as the shaking and palpitation, point rather to a functional derangement, a conversion neurosis

S C., a woman, aged 33, when seen in May 1931, had been having attacks of sticking precordial pain radiating to the left arm for one year, which occurred both at rest and on excitement. Two days after the sudden death of a friend from heart disease she had an attack of severe pain in the back of the left shoulder, radiating down the left arm, and a choking sensation in the neck. The pain lasted two hours. Intermittent attacks of similar pain persisted for two weeks to the time of her first visit. The heart sounds were of good quality, there was a cardiorespiratory murmur at the base of the heart, fluoroscopy revealed no cardiac enlargement. The blood pressure was 105 systolic, 75 diastolic. The electrocardiogram was negative. She was then well for two years, when, following the death of a cousin's baby, sticking precordial pain again developed, radiating to the left shoulder and arm, unrelated to exertion. She soon recovered and was again well for two years, when, following a miscarriage, she became irritable, cried readily, and had indigestion with vomiting and choking. The slightest aggravation or talking provoked sharp substernal pain, which radiated to the left arm and fingers. On walking five blocks she experienced needle-like chest pains, dyspnea and heaviness in the lower part of the sternum which compelled her to rest. Physical and roentgen examinations in January 1936 again were negative. The blood pressure was 110 systolic, 70 diastolic. The electrocardiogram was negative and unchanged.

Although precordial pain radiating down the left arm, associated with a sense of choking at times provoked by walking, suggests angina pectoris, the youth of the patient, the repeated appearance of symptoms following psychic trauma, the free intervals, and the absence of objective signs after five years point rather to a benign form of precordial pain.

G F., a woman, aged 45, while in a motion picture theater sixteen months before her first visit had an attack of severe pain in the left upper parasternal region and under the left breast, preceded by an uneasy nervous feeling in the left side of the chest. She was confined to bed for six weeks under the supposition that she had had a heart attack. She was subsequently warned by one of her physicians against climbing one flight of stairs lest she suddenly drop dead. After getting out of bed, she noted sternal choking on walking, radiating to the left breast and around the back, lasting ten minutes. Two weeks before her visit to us, following excitement, she experienced pain in the lower part of the sternum radiating to the left shoulder and left elbow, lasting about ten minutes. She complained of a constant precordial soreness and weakness, with exaggeration of the symptoms on slight activity. Physical examination was negative. The blood pressure was 118 systolic, 80 diastolic.

An electrocardiogram showed only left axis deviation. She was reassured and told that she had no heart disease. She was advised to increase her activities, and tincture of valerian was prescribed for the pain. She returned ten months later saying that she had become progressively better, especially with the use of valerian. She now walks six or eight blocks and becomes tired but has no chest pain. There is mild intermittent sticking pain in the left side of the chest unrelated to food or exertion but definitely related to changes in weather. She says that the strongest pains in the chest are readily relieved by the application of an electric pad. Physical examination and the electrocardiogram are unchanged.

In this case the diagnosis of a heart lesion and the enforced bed rest following an attack of benign chest pain led to persistent attacks of precordial pain, with radiation to the left arm and substernal choking, for a period of sixteen months. The symptoms were relieved by reassurance and suggestive therapy.

T G., a woman aged 44, stated in November 1935 that for two months exertion and excitement had induced attacks of midsternal pressure lasting from five to ten minutes. Walking five blocks or so brought on fatigue and dizziness, and if she

quicken her step substernal pressure set in, forcing her to stop and rest for a moment. Under emotional stress she experienced substernal pressure, she became dizzy, her hands became ice cold, and she shivered and often cried. She had serious financial worries, her husband's income being only \$15 a week. Physical examination was negative except for many extrasystoles. The blood pressure was 140 systolic and 90 diastolic. The electrocardiogram showed only many ventricular extrasystoles.

The outstanding fatigue and dizziness together with the occurrence of coldness, shivering and crying in the attacks are typical of an anxiety state.

Chest pain may develop in women who have nursed patients with coronary artery sclerosis or who have lost a relative or close friend from this disease. The readiness with which they may develop the classic pattern of angina pectoris is remarkable.

R R., a woman, aged 49, felt responsible for the sudden death of her husband from heart trouble because she had not called a consultant during his final illness. Immediately after his death she complained of pain to the left of the sternum and in the left arm. She stayed in bed for three months while the pain continued steadily. Subsequently she would become weak and shaky on slight excitement. Physical examination revealed no abnormalities except slight dilatation of the aorta. The electrocardiogram showed only left axis deviation. Fourteen months later her physician reported that she was feeling well and had lost all the chest pain.

P R., a woman, aged 47, stated in March 1932 that for six months she had had an almost constant gripping sensation to the left of the sternum, radiating to the left arm as a sense of weakness, aggravated by exertion. Nine days before her visit she was awakened by severe squeezing pain to the left of the sternum, radiating to the left elbow and left posterior part of the chest. The pain was of one hour's duration and was followed by residual weakness. Soon after the pain subsided she became aware of the action of her heart. She experienced at times sudden throbbing of the heart, accompanied by a momentary shock in the head. When she walked two or three blocks, palpitation set in, which caused her to rest. She was stout, and there was moderate left ventricular enlargement. The heart sounds were strong. There was a systolic murmur at the aorta and at the apex. The blood pressure was 135 systolic, 80 diastolic. The electrocardiogram showed left axis deviation, low voltage and a low T wave in lead 2. The diagnosis of coronary artery sclerosis was made at that time. She was not seen again until almost four years later, in January 1936. For three years she had felt fairly well, having had only occasional drawing pains in the left side of the neck and to the left of the sternum, at times awakening her from sleep and lasting from one to two hours. During the six months preceding her second visit she often awakened in the morning with a sinking feeling and weakness, lasting several minutes and relieved by brandy or spirit of ammonia. Two days before this visit she felt weak before retiring and was awakened early in sleep by a sinking feeling, as she described it, which kept her awake all night. The following day she had unusual drawing pains in the neck and chest. She suggested that her present symptoms and attacks were of somewhat the same nature as those four years before. At present walking causes a sinking feeling and compels her to rest a few minutes, partly relieved by taking a deep breath. This necessity of taking a deep breath recurs frequently. Physical examination at this time was unchanged, except for some increased voltage of the T wave in lead 2.

In the light of the four year follow up and a closer analysis of the symptomatology with its characteristic functional stigmas, the original diagnosis of coronary artery sclerosis is most questionable. Of great importance in the entire sequence of events and in arriving at a diagnosis is the history of the illness of her husband, who was observed during the same period. He was first seen in November 1931 complaining of leg pains of several years' duration. Occasional precordial pain and oppression developed in December. In February 1932 he experienced a classic coronary thrombosis with positive electrocardiographic signs. He then was symptom free for three years, but during the past year he had a recurrence of pain in

the legs which occasionally awakened him from sleep. The development and remission of chest pain in the wife paralleled closely the evolution of symptoms in the husband.

The problem becomes more difficult when such pain occurs in women with hypertension, but also in these cases true angina is far from frequent, although precordial pain is very common. This is not astonishing in view of the marked disturbances of the vegetative nervous system that occur in most women with essential hypertension.

A G., a woman, aged 42, seen in August 1930 had had the gallbladder removed when she was 32. At the age of 22 she experienced drilling precordial pain radiating to the left arm which was constant for some time and has always recurred with excitement. At the age of 38 following severe agitation, precordial pain radiating to the left arm set in and forced her to bed for two weeks. For the two months preceding her first visit in 1930 she had attacks of numbness in the hands followed by epigastric pressure which radiated to the left parasternal area. With this the left arm became numb and weak, the fingers white and cold. The attack was often accompanied by tremor of the whole body. On examination her face was flushed and she was nervous. The heart on fluoroscopy showed slight enlargement of the left ventricle and elongation of the aorta. The heart sounds were strong. The blood pressure was 150 systolic, 105 diastolic. The electrocardiogram was negative, showing only left axis deviation. The following month she reported that tincture of valerian had relieved her attacks. In 1932 while at the office she had one of her attacks. The face was flushed, respiration and pulse were rapid and she cried. She was not seen again until four years later in November 1935. Three weeks previously she had experienced sudden retrosternal pressure radiating to the left shoulder which lasted for half an hour and was followed by persistent precordial pain and weakness. Walking did not aggravate the pain. Physical examination at present showed heart sounds of good quality and a systolic murmur at the aortic area. The blood pressure is 180 systolic, 100 diastolic, the electrocardiogram is unchanged.

F A., a woman, aged 50 seen in July 1932 had had a thyroidectomy two months previously for a simple goiter of many years' standing. The menses were regular. One week previously, while lying awake in bed she had experienced a severe, cutting pain from the midsternum through the chest posteriorly, lasting half an hour, followed by a succession of mild fainting spells. A constant gnawing pain in the midsternum appeared and lasted all the week. She was markedly obese. There was moderate left ventricular enlargement on fluoroscopy. The heart sounds were strong. The heart rate was 92. The blood pressure was 160 systolic, 110 diastolic. The electrocardiogram was normal, showing only left axis deviation. In November 1935 a right nephrectomy for hypernephroma was performed. When she was seen in December she stated that she occasionally had sharp pains under the left breast radiating through to the back, unrelated to walking or other exertion. She still had choking spells lasting a moment unrelated to effort. The physical examination and the electrocardiogram were unchanged.

COMMENT

Case histories such as these could be multiplied many times. We present them with a certain hesitancy, so strongly do some of them suggest the presence of coronary artery disease. However, we have yet to see a woman with precordial pain, whether associated with hypertension or not, in whom the subsequent course of the illness indicated that our original diagnosis of benign heart pain had to be revised because of the development of objective physical or electrocardiographic signs of disease of the coronary arteries. And we have had the opportunity of following many patients for from two to five years. On the other hand, in not a few we have been compelled to discard an original diagnosis of angina pectoris in the light of the subsequent events. This record is not evidence of rare diagnostic acumen but rather is due to our awareness of the rarity

of coronary disease in women, which made us weigh each case very carefully before placing it in this category. Knowledge of the frequency of disease is a great aid in diagnosis.

The clinical picture that simulates angina pectoris is by no means new. The nineteenth century literature is replete with papers on false or pseudo angina, vasomotor angina, reflex angina, or secondary angina pectoris. The case reports reveal a preponderance of women. But knowledge of coronary artery disease in those days was very imperfect, so that many errors of diagnosis crept in. On the other hand, the practitioner of today has been drilled so thoroughly to associate heart pain with coronary artery disease that many of the niceties of diagnosis known to previous generations of physicians have been forgotten.

What are the features that distinguish this benign form of precordial pain from that of true angina pectoris? First of all the personality of the patient gives a clue. Women with benign precordial pain are usually anxious and high strung in contrast to the stolidity so often encountered in men with coronary artery disease. The symptoms are very prone to follow emotional or economic disturbances at home, such as the illness or death of a child, marital difficulties or financial stress. These women are always rising and even between attacks of severe pain they complain of lesser continuous pains, palpitation, dyspnea, vertigo and weakness. Frequently they take to bed after an attack of chest pain and the duration of bed rest is out of all proportion to the severity of the attack. The usual patient with coronary artery disease feels well between his seizures.

Diagnosis is greatly aided if the physician is able to witness an actual attack of pain. This often bears the marks of hysterical seizure. The patient feels faint, her voice becomes weak, she grasps for breath and she tosses about and then falls back in a simulated faint, the eyes partially closed and the eyelids twitching unresponsive to commands but aware of her surroundings. Often the limbs are rigid or there may be a shivering of the whole body—the so-called nervous chill. There may be palpitation, the hands and feet may be cold and pale, and the face flushed. The attack wears off gradually. Far too often the physician who is called administers a hypodermic injection of morphine and tells the patient and her family that there has been a heart attack. Not infrequently this diagnosis finally fixes the patient's attention on her heart and ever after all symptoms are referred to this organ. The differential diagnosis should not be difficult for, as Allbutt¹⁴ says, "these faintnesses, palpitations, gaspings, stiflings, bodily agitations, hyperesthesias and psychical commotions are as wholly unlike the ruthless grip of angina pectoris as their frantic alarms are unlike its silent passion." Even in milder attacks there are usually enough vasomotor signs accompanying the pain to make the diagnosis clear.

The character of benign precordial pain often serves to distinguish it from that of true angina pectoris. It is more apt to be diffuse or confined to the region of the apex, it is usually sticking and cutting in character rather than pressing. But these distinctions are not absolute for either type of pain occurs in either condition. Radiation of the pain is of no differential value. Pain in the left shoulder and radiation down the left arm, or a sense of numbness or heaviness of the left

14. Allbutt, T. C. *Diseases of the Arteries Including Angina Pectoris*. London: Macmillan Company, 2: 235, 1915.

arm, are very commonly associated with benign precordial pain. Both the precordial and the arm pain in these patients, however, are much more constant than is the rule in angina pectoris and are less commonly immediately provoked by exertion or even emotion. More usually they are later after-effects. After a severe attack of benign precordial pain one often observes prolonged residual pain or a precordial ache for days after the attack. This is unusual when there is organic disease, even after a coronary thrombosis. Precordial hyperesthesia is very commonly associated with benign chest pain. The patient cannot lie on his left side, he complains of the pain caused by the pressure of the stethoscope. Often during auscultatory examination the patient will halt the physician by saying "That is where my pain is, right under your stethoscope." Often this tender area is located over the fourth left costal cartilage. Such a tender cartilage may be so disabling and annoying that the term perichondritis has been employed to describe the symptomatology.

Kilgore¹⁵ and Baker¹⁶ have published studies of these chest pains. Baker followed forty-three women and nine men with inframammary pain for many years. She noted the intermittent sticking character of the pain, its indefinite relation to effort and its tendency to occur when the patient is tired and after exertion. She found that long remissions from pain are frequent and that relapses usually coincide with some illness or with extra physical or mental strain. In 392 consecutive cases she observed this pain in 42 per cent of patients without heart disease and in 22 per cent of those with organic heart lesions.

Women often experience chest pain while doing their housework but not while walking. This discrepancy in response to different forms of exertion may be due to the nature of household work, which calls for repeated bending while lifting children, cooking, reaching into the icebox, sewing, sweeping and scrubbing floors. Even in the absence of distinct osteo-arthritis of the spine one might expect a variety of chest pains and aches from repeated torsions of the chest and spine, especially in women over 40 in whom obesity and poor posture are so common. Many of these women feel better when they are walking in the open. In men chest pain induced by occupational exertion is usually experienced as well when they walk, unless a definite postural cause of the pain exists.

The most characteristic feature of true anginal pain is its direct relationship to effort or emotional strain. The patient reports very simply and without dramatic embroidery that walking or lifting or excitement induces some form of sensation in the chest or at times in the arm alone, which compels an arrest of activities. After a few moments' quiet the distress is gone and the patient feels as well as ever. In contrast to this simple clear story the individual with benign precordial pain gives a highly colored version of sharp chest pains with all kinds of associated symptoms and vasomotor disturbances. She is not compelled to immobility by the disturbed functioning of her heart but lies down and rests and is overcome with bodily weakness, largely because of her apprehension.

Palpitation is commonly associated with benign heart pain. It may accompany the attack or occur during

periods of freedom from pain. Commonly precordial pain comes at rest, palpitation on exertion. Often these patients are conscious of the beating of their hearts while resting in bed. Palpitation is rarely associated with true angina pectoris unless the attack is induced by a paroxysm of tachycardia or unless the anginal syndrome is complicated by hyperthyroidism. Patients with benign heart pain experience pain first, this is followed by apprehension and palpitation. When an attack of angina pectoris is released by a paroxysm of tachycardia, the patient first experiences palpitation and later on the precordial pain.

Treatment of benign precordial pain is difficult and often unsatisfactory. Some patients are relieved by simple reassurance, by the affirmation that they have no organic heart disease. In others, suggestive therapy is helpful, but all too often these simple measures fail. Frequently much harm is done by directing treatment to the heart or by prescribing drugs such as digitalis or aminophylline, which the patient soon discovers are cardiac remedies. Still greater is the havoc caused by an error in diagnosis, by the physician's statement, no matter how qualified, that the pain does arise in the heart. Many of these patients need skilled psychiatric treatment and would be much better off in the hands of psychiatrists than of cardiologists.

If the physician elicits the clinical history with the preconception that the patient has true angina pectoris, a fairly typical story of this disorder is usually obtained. The greatest care must be taken to avoid leading questions, to discover the real nature of the pain, its location, its duration, and its mode of onset and offset. Far too many patients are given angina pectoris by their physicians. Not a week passes but we see several patients invalided by an erroneous diagnosis of coronary artery disease. Such mistakes at times are due to ignorance, more rarely to cupidity. Most often the error can be traced to the fear of blame if death or serious illness follows after the physician has declared the patient free from organic heart disease. It takes courage to tell a patient with symptoms suggesting heart disease that he has no organic cardiac lesion.

The damage that can be done by a well meaning physician is graphically illustrated by the following case.

A woman, aged 44, had experienced while shopping, a strong aching pain in the upper left parasternal region aggravated by deep breathing. The pain was of about ten hours duration. She was kept in bed for three weeks and had mild recurrences of the pain during this period. Five weeks after the original attack a roentgenogram of the chest and an electrocardiogram were negative. A diagnosis of coronary thrombosis was made and communicated to the patient and her husband. A second complete examination five months later was also negative. She continued to have pain at intervals. It was a dull ache, quite persistent, which did not come immediately after exertion but some hours later. It would come in the evening after a heavy day, for instance. When we examined the patient ten months after the onset we found that she was nervous and apprehensive and was constantly blinking her eyes. The cardiovascular examination, including the electrocardiogram, showed no evidence of disease. The history, the nervousness and the negative examination indicated that there was no organic heart disease. The correctness of the diagnosis was supported by the manner in which it was received by the patient, her husband and her physician. Although it was impossible to discover the complete psychogenic background of the disorder, it was clear that the patient did not wish to lose her conversion neurosis, which ensured the solicitude of her husband and family, the husband, it appeared resented the fact that his wife did not suffer from serious organic heart disease, the physician wrote us that our

16 Baker Doris M. Left Inframammary Pain. *Lancet* 1: 1280 (June 14) 1930.

diagnosis might possibly be correct, but he would never take the responsibility of allowing the patient to incur the dangers of cardiac overstrain, and insisted on keeping her a chair-ridden invalid

The relative unusualness of coronary artery disease and the frequency of benign precordial pain in women should lead to great caution in the diagnosis of coronary artery disease in women in the absence of hypertension or diabetes. This applies as well to many women in the fifth decade of life with unstable blood pressures and transient rises to 160 or 170 millimeters of mercury. The fluctuating blood pressure level may be only one expression of the many vasomotor instabilities associated with the menopause and does not have the same significance as a maintained arterial hypertension. Even in the presence of hypertension in women, true angina pectoris is much less frequent than is benign precordial pain. However, coronary artery disease does occur at times in women with normal blood pressures who are free from diabetes, particularly in women over the age of 60 who have generalized arteriosclerosis. Isolated cases in young women in the absence of both hypertension and diabetes have been reported.¹⁷ When coronary artery disease occurs in women its course and prognosis are much like those in the male sex.¹⁸ The view that angina pectoris in women is less serious than in men is based on incorrect diagnosis on the inclusion of many cases of benign precordial pain with those of true angina pectoris.

A minor point of practical clinical interest arises from this study. At times the differential diagnosis between coronary thrombosis and pulmonary embolism may be difficult. From an experience similar to that presented in this paper, Averbuck¹⁹ has pointed out that "when the clinical picture suggesting coronary artery thrombosis occurs in a female patient who has neither arterial hypertension nor diabetes, a pulmonary embolus should be suspected." This point is made because of the relative frequency of pulmonary embolism in women under the age of 50, particularly in those who have been subjected to gynecologic operation.

The facts presented in this paper emphasize the need for further study of the relationship between arterial hypertension and coronary artery sclerosis. Coronary artery disease is much more common in men than in women. Arterial hypertension is more frequent in women than in men. Only 50 per cent of men with coronary artery disease have hypertension, whereas about 90 per cent of women with coronary artery disease have hypertension. Yet even in an office practice devoted mainly to cardiovascular diagnosis, only a third of the women with hypertension have symptoms of coronary artery disease. The connection, therefore, between hypertension and coronary artery disease is not a direct one. Hypertension is not the cause of coronary disease but simply accelerates its development. The designation "hypertensive cardiovascular disease," so commonly employed to describe these disease states, is a poor term. It assumes a necessary and fundamental connection between the two disorders. Their true nature can best be discovered by studying uncomplicated coronary artery disease in men and uncomplicated arterial hypertension in women. These apparently represent "pure forms" of these two conditions.

SUMMARY

1 Among patients referred for cardiovascular diagnosis, coronary artery disease was 4.9 times as frequent in men as in women.

2 All but 7.7 per cent of 169 women with coronary artery disease had either arterial hypertension or diabetes mellitus.

3 Coronary artery disease is infrequent in women, particularly in those under the age of 50, unless there is an associated arterial hypertension or diabetes mellitus.

4 Mistaken diagnosis of coronary artery disease in women are common because of the erroneous interpretation of symptoms, such as precordial pain with or without radiation to the left arm, a sense of choking and fear of death. Such symptoms are common in the absence of organic heart disease.

ARTIFICIAL FEVER IN THE TREATMENT OF GONORRHEAL OPHTHALMIA

W. T. HASLER, JR., M.D.
AND
LOUIS SPLIKTLER, M.D.
DURHAM, N. C.

Fever as a therapeutic agent was introduced in 1918 by Wagner von Jauregg¹ who reported use of malaria in the treatment of dementia paralytica. Soon, other fever producing substances were being used such as intramuscular milk and peptone streptococcus and typhoid-paratyphoid intravenous vaccines. With these methods the temperature is uncontrolled and generally of short duration unless the divided dose method of intravenous typhoid-paratyphoid vaccine is employed.

Fig. 1—Cabinet for treatment

Within the past seven years the therapeutic use of accurately controlled fever produced by physical means has slowly but surely supplanted the uncontrolled methods.

Diathermy, radiotherapy, air conditioned cabinets, inductothermy and radiant energy may be used. We employ the latter because of its simplicity, low cost, and

relative comfort for the patient. A complete description of the cabinet is reported elsewhere.³ Briefly, it consists of a cellotex lined cabinet, heated by seven 120 watt carbon filament bulbs, which fits over a bed and encloses the reclining patient completely except for his head (fig 1). For the treatment of ophthalmologic conditions a moist towel and an electric pad cover the eyes in order to maintain a high temperature.

Careful observation of the patient's condition before and during the treatment is absolutely essential, and only those who are willing to spend the time to observe the reactions should attempt this form of therapy. It must be emphasized that careful selection of the patient be made and contraindications to treatment noted, namely, cardiovascular, renal and liver disease, and a

greatly debilitated, but in the fourth no apparent contraindications to fever therapy were present.

The physiologic reactions and the care of the patient during the therapy are described elsewhere.⁶ During the treatment the patients receive subcutaneously or drink from 3 to 4 liters of water and from 10 Gm (children) to 25 Gm (adults) of sodium chloride supplied in the form of capsules or in a 0.6 per cent solution. Restlessness is allayed by sedatives, such as bromides or codeine. A typical chart showing the temperature, pulse, respiration and blood pressure of a patient during the treatment is given in figure 2.

Fever therapy has been used in various eye conditions: malaria for interstitial keratitis⁶ and in the control of optic nerve atrophy,⁷ and fever induced by

Fig 2—Temperature pulse respiration and blood pressure of a patient during treatment

history of intolerance to heat, such as sun stroke. The infrequent severe reactions include persistent vomiting, circulatory collapse, tetany and convulsions. Although we believe that the benefits derived from the hyperpyrexia therapy outweigh the risk, it should be emphasized that the latter occur. Forty-nine deaths have been reported in a total of 4,809 patients treated (0.6 per cent).⁴ At Duke Hospital approximately 430 fever treatments (at temperatures varying from 40 to 41.5 C) have been given to 280 patients (thirty-three children, 247 adults). Four deaths have occurred (1.4 per cent). One of these patients had carcinomatosis, another had a history of sun stroke, the third was

physical means for corneal ulcer, acute iritis⁸ and ocular syphilis.⁹ However, we have found only two reports of the treatment of gonorrheal ophthalmia by controlled

fever.¹⁰ As fever treatment of gonorrheal infections in various parts of the body is beneficial and as the lethal death time of *Neisseria gonorrhoeae* at 41.5 C (106.7 F) varied between six and twenty-four hours,¹¹ we treated six cases of gonorrheal ophthalmia with radiant energy (summarized in the accompanying table).

COMMENT

Treatments for five hours at 41.5 C or lower (never higher) may be given instead of the twelve hourly period, which requires two or three shifts of nurses. However, more treatments will be required. During the first two or three hours of fever the conjunctival discharge diminishes rapidly in amount and the edema becomes less, allowing the irrigating solution to reach all parts of the conjunctiva. Toward the end of the treatment the changes have progressed so that the cornea, which perhaps could not be seen well before treatment, because of chemosis, now can be more clearly

of ulceration of the cornea and ophthalmitis. In case 6 a conjunctival flap was required because of a spreading ulcer. We believe this patient's cornea would have perforated and an ophthalmitis resulted without fever treatment. Only two of these patients had simple conjunctivitis, while four had varying degrees of corneal ulceration. The average length of hospitalization for these six patients was 15.3 days, including the post-operative days. The average length of hospitalization for six patients having gonorrheal ophthalmia treated by irrigations alone or together with intravenous typhoid vaccine was 25.2 days. In the four patients having genito-urinary infections the discharge ceased and gonococci disappeared from the smears.

SUMMARY

Necessary precautions for the safety of the patient include a careful study of his general physical condition before the treatment and careful observation while the

Analysis of Cases of Gonorrheal Ophthalmia Treated with Fever

| Case | Age | Race and Sex | Duration of Infection Before Treatment, Days | Gram Negative Diplococci in Eye Discharge | Condition of Eyes on Admission to Duke Hospital | Results after First Treatment 12 Hours at 41.5 C (106.7 F) | Results after Second Treatment 12 Hours at 41.5 C (106.7 F) | Condition on Discharge | Days in Hospital |
|------|--------|--------------|--|---|---|--|--|--|------------------|
| 1 | 7 yrs | Colored ♀ | 8 | + | I lids of left eye swollen and red; discharge profuse; corneal ulcers | Swelling and discharge absent; smears positive | Treated 12 hours; swelling and discharge absent; smears persistently negative; ulcer healing | Corneal ulcer healed; vision good | 11 |
| 2 | 5 mos | Colored ♂ | 4 | + | I lids of left eye swollen and red; discharge profuse | Swelling and discharge practically absent; smears negative; left eye cleared | Treated because of infection of right eye which cleared; smears persistently negative | Cured | 11 |
| 3 | 6 yrs | White ♂ | 8 | + | Both eyes red and swollen; corneal ulceration; right eye with prolapsed iris; corneal ulcer; left eye | Swelling and discharge practically absent; smears positive | Discharge and swelling absent; smears positive; becoming negative one week later | Right eye lost; corneal ulcer; left eye healed | 20 |
| 4 | 20 yrs | White ♂ | 7 | + | I lids of right eye swollen and red; profuse discharge | Swelling and discharge absent; smears persistently negative | Not required | Cured | 11 |
| 5 | 21 yrs | Colored ♂ | 8 | + | I lids swollen and red; deep marginal erosion; corneal ulcer; right eye discharge profuse | Swelling absent; slight serous discharge; smears persistently negative | Not required | Eye enucleated | 12 |
| 6 | 30 yrs | Colored ♂ | 16 | + | I lids swollen and red; purulent discharge; left eye deep corneal ulcer | Swelling and discharge slight; ulcer still present; smears negative | Not required | Conjunctival flap necessary; vision poor | 21 |

observed. Irrigations may be continued with ease for the next few days. Gonococci, which still may be present, seem to be less resistant to antiseptics. Though irrigations may not be necessary, it is wiser to carry them out at intervals of four hours.

If the infection is not eradicated by the first treatment, the inflammatory process may recur in two or three days, when a second treatment should be given. Two treatments at 41.5 C for from nine to twelve hours have resulted in bacteriologic cures in cases 1 and 2. In case 1 the corneal ulcer healed. In case 2 the simple conjunctivitis healed entirely. In case 3 negative smears were obtained one week after the second treatment. One eye was lost as the result of a perforated cornea, but the corneal ulcer of the other eye healed. In the other three cases one treatment produced negative smears. In case 4 healing occurred without any residua. In case 5 enucleation was necessary because

treatment is being carried out. Contrindications include cardiovascular renal and liver disease, and a history of intolerance to heat, such as sun stroke.

Six patients having gonorrheal ophthalmia were treated. In five, the organisms disappeared after one or two treatments. In the sixth the gonococci disappeared one week following the second treatment. This method of treatment is especially indicated when corneal complications are present.

We believe that fever therapy, when carefully carried out, is distinctly beneficial in gonorrheal ophthalmia. It cruses subsiding of the inflammation and disappearance of the organisms accelerates healing and shortens the stay in the hospital.

A Man's Waist Measure—According to a rule of thumb: "For every inch by which a man's waist measure exceeds his chest measure subtract two years from his life expectation." Any such rule is probably too simple to show fully the danger of extreme overweight, for the data tend to indicate that with increasing weight and age the mortality increases at an accelerating rate.—Sherman, H C. Food and Health. New York, Macmillan Company, 1934.

FRACTURE OF THE NECK OF
THE FEMURSIR ROBERT JONES LECTURE IN ORTHO-
PEDIC SURGERYF J GAENSLER MD
MILWAUKEE

Fracture of the neck of the femur has been receiving increasing attention during recent years because of the general recognition of the fact that the results of treatment are far from satisfactory. My special interest in this field was aroused some seven years ago, through the failure to recognize an impacted fracture. The restoration of perfect function and of solid bony union in this case, in spite of a very brief period of protection from weight bearing, provided the stimulus for further study of this type of fracture. It is believed that the impacted fracture holds the key to a solution of some of the most important problems involved in the treatment of fractures of the neck generally, and that it is from the story of the clinical course of the impacted fracture that one can best understand the underlying principles involved in the healing process.

The reasons for the apparently uniformly successful results in impacted fractures of the hip of the type shown in figure 1 may be enumerated as follows:

- 1 Practically complete apposition of fragments
- 2 Complete immobilization by reason of impaction
- 3 Probable absence of serious damage to vessels carried by the capsula reflexa
- 4 Absence of interposed capsule
- 5 Resumption of early motion
- 6 Relative infrequency of aseptic necrosis

The surgeon, of course, will have no control over circulatory damage or inclusion of the capsule at the time of injury, but if the capsule can be released, as described later, it is believed that conditions are established conducive to early repair of vessel damage with probable avoidance of aseptic necrosis. The other points mentioned may be regarded as essential conditions that must be met or approached by any method of treatment hoping to compete in its results with those noted in the healing of impacted fractures. Assuming that reduction, by whatever method, has been accomplished, it is believed that adequate immobilization is secured more readily by means of internal fixation than by conservative methods now in general use.

A brief report of the case that provided the incentive for the present study seems warranted. I was called to see a woman, aged 52, who had fallen and injured her hip, Jan 1, 1929. There was no shortening, rotation outward or other deformity. Motion was free and painless except at extremes. She was able to stand, to walk and even to squat down with little difficulty. A diagnosis of contusion of the hip was therefore made. A roentgenogram taken three days later showed a subcapital, impacted fracture. Since the patient had been permitted to walk without apparent detriment previous to a diagnosis of fracture, walking was continued, and the patient made an uneventful and complete recovery. My associates and I have seen seven other similar cases since then in all of which recovery occurred with relatively brief and simple support. In all there was impaction and in all there was a slight valgus deformity

of the neck, so that weight was transmitted more perpendicularly and without the shearing action at the site of the fracture.

It was felt that the association of the valgus deformity with impaction was an essential factor in permitting this early function and that possibly this feature might be utilized in the treatment of fractures of the neck that were not impacted. Studies were therefore undertaken in the anatomic laboratory to determine what maneuver might be necessary to produce reduction with impaction and a slight degree of valgus to minimize the shearing force which it was believed was a potent factor in the production of nonunion. Eighteen dissecting room specimens, consisting of the intact femur and the corresponding half of the pelvis, were utilized. The muscles in these specimens had been cut away for the most part, but the capsule was generally intact. The upper portion of the pelvic half was countersunk in concrete and reinforced with wire mesh, likewise the lower end of the femur, including the con-

Fig 1—Subcapital impacted fracture on the right. Note the slight valgus deformity resulting in weight being borne more perpendicularly and in reducing the shearing action at the site of the fracture.

dyles and the lower fourth of the femur. The specimens were then put in a testing machine (fig 2), by means of which gradually increasing pressure was applied until a fracture occurred. The descent of the crushing weight was very slow, about fifteen hundredths of an inch to the minute. Fracture generally occurred in about five minutes. During this application of pressure the femur could be seen to bend slightly and fat was observed exuding from the shaft. All the fractures occurred at the neck, none in the shaft, the force varying from 1,300 to 3,000 pounds. In the majority the fracture line extended vertically through the neck from the upper outer margin of the head toward the lesser trochanter in a line parallel with the shaft, thus producing an oblique fracture through the neck (fig 3).

In this process the capsule was not infrequently torn when the neck suddenly gave way, the tear invariably involving the posterior portion of the capsule, often extending to the superior portion. Not infrequently the capsule was caught between the fragments, as

shown in figure 4 Attempts to produce impaction and slight valgus during abduction and traction in extension, the Whitman position, with pressure or a blow against the trochanter, with any force within reason, were unsuccessful This experience tallies with the experimental work of Gill¹ and of Snodgrass² The failure to obtain impaction is due to the fact that the

Fig. 2—Method of producing fractures of the neck of the femur The upper portion of the right pelvic half and the lower end of the femur are fixed in reinforced concrete Gradually increasing vertical force is applied

cortical bone of the neck is very dense and compact, thus lending itself very poorly to a meshing of the fracture surfaces It must be remembered however, that none of the fractures produced experimentally were subcapital, the usual type seen in impacted fractures Had subcapital fractures been produced experimentally, it is quite likely that efforts at impaction might have been successful since the cortical bone in the extreme upper portion of the neck is very thin and would allow meshing of the fractured surfaces with less difficulty In a fall in the living the force producing impaction is probably greater than any force that would be justified in an artificial impaction, because of the danger of fragmentation In these endeavors at reduction and attempted impaction it was further observed that the anterior portion of the capsule was never torn and that in abduction of the hip in the extended position the Y ligament, as pointed out by Whitman³ aided in bringing the fractured surfaces together by its action as a fulcrum at the same time preventing any gaping of the fracture line below Incidentally, actual impingement of the trochanter against the ilium was not observed This again coincides with the experience of Snodgrass in his work on the cadaver

The relation of the capsule to the fracture was of special interest As already stated, the capsule was sometimes found interposed It should be recalled that

the capsule is attached above to the margin of the acetabulum and below to the intertrochanteric line, thus completely covering the neck anteriorly Posteriorly the capsule is attached to just below the middle of the neck, the lower third of the neck not being covered The capsule may thus be described as a skirt suspended from the margin of the socket, long in front and short behind In fractures through the neck the capsule is apt to be torn close to the lower posterior attachment, the hem of the skirt As the lower fragment is pushed up at the moment of fracture it carries the capsule with it, and as the femur is pulled down in efforts at reduction the capsule is wiped into the fracture cleft and is held securely It is interesting to note that, while efforts to release the capsule by traction and extension failed release was readily and invariably accomplished by flexion of the hip to 90 degrees This is explained by the shortness of the skirt posteriorly As the flexion increases the fragments are pulled away from the capsule since the upper attachment of the latter remains fixed to the acetabular margin

In a number of instances it was found that traction on the extended extremity was ineffectual in restoring full length, owing to locking of the fragments, while when upward traction was made with the hip flexed full length was readily restored It appeared, therefore, that withdrawal of the capsule from between the fractured surfaces as well as restoration of length, at least in some cases could be more readily accomplished by the maneuver of flexion and upward traction than by traction in extension and abduction In a few instances it was found that while shortening, that is, longitudinal displacement, was readily corrected, anteroposterior displacement sometimes persisted, the trochanter portion usually lying in a plane anterior to the normal By alternating manual pressure on each side of the trochanter the fragments could usually be

Fig. 3—The common type of fracture of the neck produced as shown in figure 2

brought to settle in proper position, thus correcting the anteroposterior displacement and producing practically perfect reduction

The realization that impaction to say nothing of impaction combined with slight valgus, was difficult or impossible to obtain led to an abandonment of efforts in this direction This much, however, was learned that in the laboratory practically anatomic reduction was readily obtainable by upward traction, as in the

Leadbetter⁴ procedure. The method differs, however, from Leadbetter's in that extension is not added as a further step, since reduction is completed with the upward pull and further manipulation is unnecessary.

The problem, then, was to devise means of fixing the fragments immovably, with the hip and knee maintained in flexion of 90 degrees. This was accomplished

Fig 4—Inclusion of the capsule after reduction of fracture of type as shown in figure 3

in the dissecting room specimens with three knitting needle spikes introduced under direct vision, the technic being modified for subcutaneous introduction of the pins in the living, as described elsewhere.⁵ Since the extremities obviously could not well be held by an assistant during the nailing process, which required considerable time the limbs were supported from overhead bars, some 8 or 9 feet above the floor level, high enough to allow ample clearance for the portable x-ray machine then used (fig 5). This method of overhead support proved efficient, though cumbersome. About this time I was called to reduce a hip in a patient in a distant city. Because the overhead supports before used were not portable, some other plan for supporting the extremities had to be devised. Accordingly, plaster half-shells were made, from midthigh to toes supporting both extremities in the position of flexion of both hips and knees at 90 degrees. The plaster half-shells were in turn supported by adjustable pedestals, as shown in figure 6. This form of support has proved satisfactory in that it is adjustable and portable. It is important that the pelvis does not rest on the table in order that one may have the benefit of continuous body weight traction, which serves to insure maintenance of proper relation of the fragments during the subsequent spiking. The pedestals supporting the plaster half-shells are therefore raised so that the pelvis swings free about an inch above the table top. An added advantage of the suspended pelvis is that the flat x-ray cassette

can be placed under the patient's fractured hip (fig 7 A and B) in taking the lateral view without disturbing his position. Abduction of the flexed thigh is added to coapt firmly, or to lock the fragments and also to make possible the taking of the roentgenograms in both anteroposterior (fig 8) and lateral views without shifting the patient. A final step in the maneuver is the internal rotation of the thigh corresponding in degree to the angle of anterior torsion on the uninjured side, the average being about 12 degrees. The advantage of the abducted and internally rotated position lies in the fact that these maneuvers bring the neck parallel to the operating table and perpendicular to the table edge, materially facilitating the introduction of the spikes at proper angles.

Reduction by the maneuver described, namely, traction in flexion, appears to be based on sound anatomic and mechanical principles for the following reasons:

1 Flexion relaxes the anterior portion of the capsule and the Y ligament. It also relaxes some but not all of the important pelvifemoral muscles, as will be shown later.

2 The capsule, if interposed, is withdrawn as previously described.

3 Anteroposterior displacement if present, is readily corrected by lateral pressure, the maneuver being facilitated by the suspension of the pelvis.

4 Tendency to redisplacement is minimized because of the steadying effect of the weight of the pelvis hanging from the femurs as fixed points.

5 The position makes possible the taking of repeated roentgenograms in both anteroposterior and perfect lateral views without shifting the patient during the sometimes tedious process of spiking.

While the statement that flexion relaxes the muscles about the hip joint, facilitating reduction, would probably go unchallenged at first glance, closer study shows that such a statement must be very definitely qualified.

Fig 5—Overhead bars for support of the extremities with knees and hips flexed at 90 degrees

In order to clarify this point, the following procedure was carried out. The origins and insertions of all muscles about the hip were marked with tacks driven into a skeleton, the heads of the tacks left projecting. Elastic cords representing the individual muscles were then attached to these tacks and the difference in the length of the cords was noted in the flexed position as compared to the extended position, as shown in the accompanying tables.

⁴ Leadbetter, G. W. A Treatment for Fracture of the Neck of the Femur. *J. Bone & Joint Surg.* 15: 931 (Oct.) 1933.

⁵ Gaensler, F. J. Subcutaneous Spike Fixation of Fresh Fractures of the Neck of the Femur. *J. Bone & Joint Surg.* 17: 739 (July) 1935.

In table 1 are listed the muscles whose points of origin and insertion are approximated, with resulting relaxation favoring reduction.

In table 2 are listed the muscles whose points of origin and insertion are separated, with resulting stretching and hindrance to reduction.

It will be noted in table 1 that only the first four muscles enumerated were relaxed to any considerable extent and that, on the other hand (table 2), there was a definite and considerable elongation of the adductor magnus, the biceps, the semitendinosus and the gluteus maximus.

TABLE 1—*Muscles Shortened by Flexion of Hips to 90 Degrees*

| Gemellus inferior | 1.8 cm |
| Obturator externus | 1.2 cm |
| Piriformis | 0.0 cm |

Figure 9 shows a tracing of a lateral roentgenogram of the lumbar spine, pelvis and femur of a young man. There is noted the normal lordosis. The hip is in extension. The slightly oblique line bisecting the anterior superior spine and the middle of the greater sciatic notch is used merely as a convenient indicator of the position of the pelvis.

In figure 10 it is noted that the femur is flexed through 90 degrees. It should be observed also, however, that the pelvis is moved 48 degrees in the same direction, so that the actual flexion of the femur on the pelvis is only 90 — 48, or 42 degrees.

The tables of muscle relaxation and stretching are prepared from measurements in which the normal lordosis was undisturbed. In other words there was an actual flexion of 90 degrees. When the lordosis is diminished, as in figure 10, relaxation of the anterior muscles is diminished, but this difference is offset by diminution also in the stretching of the posterior muscles.

One may summarize the results very briefly by saying that during hip flexion the muscles lying anterior to the hip joint are relaxed while those lying posterior to the joint are stretched. It is probable that during anesthesia muscle tension may be practically disregarded and that the advantage of the flexed position recognized clinically must be attributed to the relaxation of the anterior portion of the capsule especially of the Y ligament, and of the fascia lata.

On reviewing the literature, reduction by traction in flexion is found to date back to Dupuytren⁶ who in his "Leçons orales," published in 1839 the year of his death, described the method in detail. The flexed position of the hip and knee was maintained until bony union occurred, a result which, according to his writings, occurred with regularity.

In figure 11 there is pictured the pillow support arranged according to the very careful description of Dupuytren, although no picture accompanied his text. He stresses particularly the need of having the pillows high enough to prevent the buttock from resting on the bed in order to get the proper traction effect. This method may well deserve consideration as a temporary measure in the very aged if the general condition does not warrant immediate reduction or as an alternative to

that diminishing minority who still feel that it is best to make the patient as comfortable as possible and to avoid all attempts at reduction. It would at least have the advantages of avoiding decubitus and of really making the patients comfortable, with perhaps a chance of duplicating many of the happy results reported by Dupuytren. This author stresses the point that he was the first to advocate reduction in flexion and voices his astonishment that Potts who had advocated reduction in flexion of practically all the long bones because of the advantage of muscular relaxation, had neglected to mention flexion as an aid in reduction of fracture of the neck of the femur.

In more recent times reduction in flexion was recommended by Maxwell⁷ in 1876 by Ruth⁸ in 1921 and by Leadbetter⁹ in 1933. All these authors, however, added extension as a final step in the reduction maneuver. I should like to repeat that the method I described terminated with abduction and internal rotation of the flexed hip, extension being avoided as an unnecessary further step which might conceivably produce malunion because of the constant tendency of the hip, when extended to roll out.

The need for adequate fixation is now being generally recognized but it was also recognized by many of the earlier writers among them Senn⁹ who in his interesting monograph in 1883 stressed this point particularly and suggested a method of reinforcing the external fixation of the plaster cast with a pin incorporated in the plaster and engaging the trochanter. Among Senn's conclusions the following are of interest:

The causes of nonunion are not to be found in the broken bone but in the difficulties encountered in treatment. All the various methods of treatment suggested and practiced have failed in securing perfect coaptation and uninterrupted immobilization (p. 102).

If we could keep the broken surfaces in perfect coaptation and maintain reduction and immobility these fractures would heal in the same way as impacted fractures (p. 103).

The earliest reported transfixion was in 1850 thirty years before the antiseptic era by von Langenbeck,¹⁰ who succeeded in introducing a screw through a 1 cm.

TABLE 2—*Muscles Elongated by Flexion of Hips to 90 Degrees*

incision over the trochanter, fixing the fragments in perfect position. Unfortunately his patient died of hospital gangrene but in spite of this he expressed the firm belief that this method would find favor in the future. König¹¹ in 1875, using antiseptic precautions, succeeded in nailing a fracture of the neck of the femur in a youthful individual by introducing a metal drill

through a small incision over the trochanter Trendelenburg¹² appears also to have been intrigued with the idea of internal fixation. He reports having made numerous attempts on the cadaver to introduce a peg through the trochanter without free opening of the joint. He states: "Sometimes you hit it more frequently you miss. With practice you may reach such dexterity that you can generally hit it but it is easy to go by." Because of the difficulty of striking the head

Fig 6—Extremities resting in plaster half shells which are in turn supported by pedestals adjustable as to height

with the nail, he suggested exposure of the site of the fracture from behind, drilling the outer fragment from within, removing the drill and reinserting it from without to engage both the trochanter and the head fragments under guidance of the finger. Nicolaysen¹³ reported thirteen successful cases of spiking without skin incision in 1897, using a three cornered nail driven directly through the skin without skin incision, although he used a plaster cast in addition. This was done without the use of the X-rays.

No attempt will be made to review the more recent literature, which abounds in reports of attempted internal fixation, many of the authors devising ingenious methods of spiking, either open or closed, and many with very encouraging results. Among these contributors may be mentioned Lemon,¹⁴ T. Turner Thomas,¹⁵ Smith-Petersen,¹⁶ Sven Johansson,¹⁷ Moore,¹⁸ Knowles,¹⁹ Wescott,²⁰ King,²¹ Telson and Ransohoff²² and Gaensler.⁵

Accurate reduction and complete immobilization of sufficient duration must be considered the crux of the situation. Without these essentials one cannot conceive the reestablishment of the circulation across the fracture line, and on this reestablishment healing must ultimately depend. Other factors involved in healing are favorable or unfavorable solely, or at least largely, as they affect the circulatory damage.

While apposition of one half or even one third in fractures of the long bones is usually considered sufficient to secure union and a good functional result there is no such margin of safety in fractures of the neck of the femur because of the well known fact that union is by endosteal rather than by periosteal bone formation. Schmorl²³ believes that this is due to the fact that the periosteum of the neck is entirely devoid of a cambium layer.

Reduction must be practically complete in order to supply a cross section sufficiently strong to carry the normal load. It is believed that in the vast majority of instances the circulation, impaired though it may be, is still sufficient for securing bony union, provided always that the repair process is favored by accurate apposition and perfect immobilization. When nonunion occurs it may generally be explained on the basis of interference with a circulation which under more favorable conditions would have been adequate to secure bony union. In support of this view the following considerations are deemed pertinent.

In subcapital fractures the plane of the break lies in the zone regarded by many as the most poorly supplied with blood. As a matter of fact, in the uninjured hip the subcapital area is very well supplied. A glance at dry femurs in the dissecting room will dispel any doubt on this point (fig 12). In such specimens one will find a relatively large number of good sized nutrient foramina grouped on the superior

Fig 7—The author's method of obtaining lateral view of the hip after reduction and without shifting the patient.

surface of the neck close to the head, with a few scattered foramina on the posterior and anterior surfaces. In some of these dissecting room specimens, which for the most part were derived from older people, the nutrient foramina in the foeca, the attachment of the ligamentum teres, were few in number, rather minute and indeed more often than not absent altogether (fig 13). In other words, the supply from the ligamentum teres, while variable, is frequently very

scant or absent, while that from the capsular vessels is relatively abundant. While anastomoses between these two sets of vessels has been denied,²⁵ Wolcott²⁶ has recently demonstrated by injection methods that such anastomoses do occur. In view of this extensive injury to and inclusion in the fracture line of soft parts, capsule and synovial membrane must result in serious circulatory impairment. This in part explains the frequency of nonunion in the unimpacted

Fig. 8—The author's method of obtaining anteroposterior view of the hip after reduction and without shifting the patient. Confirmatory roentgenograms in two directions have been insisted on for practically every other fracture. The procedure shown in figure 7 and here makes this possible for the neck of the femur.

cases. In the impacted cases there is in all likelihood no serious damage of the vessels and no inclusion of capsule. Immobilization because of the impaction is perfect and union is the rule. The relative infrequency or absence of aseptic necrosis in this type may also be taken as evidence of an adequate circulation. The comparatively large number of nutrient foramina for the capsular vessels carried by the capsula reflexa must be regarded as incontrovertible evidence of the abundance of blood supply in the uninjured part.

In case of fracture the situation is quite different. According to Schmorl, the blood supply from the capsular vessels may be seriously curtailed, depending on how much of the synovial membrane is peeled off from the neck and whether or not there is inclusion of the torn capsule between the fracture surfaces. In the case of capsular inclusion, which occurred in 75 per cent of his cases of subcapital fracture, he believed that the blood supply must be cut off practically completely with resulting necrosis of the head. The loss of neck frequently observed, he believes, is due not so much to rubbing of the fracture ends as advocated by Schanz, as to a resorption due to tearing of the synovial vessels impaired nutrition of the neck and inactivity. On the basis of his pathologic examinations Schmorl concludes that inclusion of capsule and synovial membrane must not be underestimated in the production of nonunion, and he raised the question whether the difficulty of impaired circulation may be offset by suitable position and fixation without operative intervention. This question should probably be answered in the affirmative, because it is more than likely that early, careful anatomic reposition of the bone fragments by the

method of flexion as already described will release the capsule and bring about restoration of fairly normal relation of soft parts thus providing proper conditions for the reestablishment of circulation, just as one expects repair of vessel damage in torn ligaments in other situations.

The frequency of nonunion in the ordinary, non-impacted cases cannot reasonably be attributed to lack of circulation. It is much more likely that the blood supply was in fact sufficient for bony union had immobilization been such as to favor repair of the circulatory damage. This is proved by the fact that the high Schanz osteotomy in cases of nonunion of long standing is followed by firm bony union at the site of the original nonunion in about 50 per cent of the cases. Schanz²⁷ had observed this late healing in old cases of nonunion and ascribed the unexpectedly happy results to the elimination of the shearing force at the site of the fracture as shown in the following quotation: 'Through the elevation of the neck the fracture site is placed below the head and the body weight no longer pushes the head downward past the fracture surface but directly against it. This provides more favorable weight bearing relations and may even lead to late bony union.' The fact that the osteotomy is well below the fracture line and that the latter is not drilled or molested in any way would indicate that the circulation was adequate for healing at the time of the original injury and that union might as well have occurred first as last had proper immobilization been attained.

Schanz's pupil Pauwels²⁸ has elaborated on this idea of elimination of shearing force and adduced a mass of convincing evidence to prove the theory of Roux²⁹ that pressure stimulates bone production while tension inhibits bone production. According to this theory the connective tissue organization of the interfragmentary clot (*Bildungsgewebe*) can be directed by means of mechanical stimuli to result in (1) bone (2) connective tissue or (3) cartilage depending on the character of the mechanical stimulus. Intermittent functional pressure will result in transformation of the precallous tissue into bone while tension and shearing forces

Fig. 9—Tracing of lateral roentgenogram of the lumbar spine pelvis and femur the latter in normal extension. Note the normal lordosis.

inhibit bone production and result in connective tissue, a principle which Pauwels regards as of the utmost significance in consideration of the healing process of fractures of the neck of the femur. In the Schanz osteotomy cases the shearing force is changed into a force of intermittent pressure by the reduction of the fracture plane from a markedly oblique to one more nearly approaching the horizontal. In fractures ade-

quately immobilized by means of internal fixation the shearing force is effectually eliminated, the thrust during weight bearing being converted into a pure pressure effect

Adequate fixation implies complete immobilization not only for the usual period of twelve or even sixteen weeks but until bony union is well under way. Every one is familiar with the cases which look promising while in plaster but which show a gradual slipping

Fig 10—The femur is flexed through 90 degrees but the pelvis is likewise flexed on the trunk through 48 degrees. The lordosis is lost. The actual flexion of the femur is therefore $90 - 48$ or 42 degrees

upward of the trochanter during the first weeks or months after removal of the plaster. This experience is so common that weight bearing is often prohibited for many months or a year. In spite of this, gradual giving way of the soft callus is observed all too frequently. This must mean that fixation in plaster or other conventional methods is inadequate. It is felt that the very slight movement allowed in the cast, especially in the case of stout individuals, no matter how carefully the cast may be molded, is responsible for a fair share of the failures. This gradual giving way is again the result of mechanical interference with the circulation and therefore with the healing process. The tendency of the unsupported hip to roll out, combined with the telescoping effect of contraction of the pelvifemoral muscles, must cause a tendency of the fracture to gape because of the repeated tension strain on the immature callus. The same lesson has been learned in the treatment of fractures of the carpal scaphoid. In this case, however, external fixation is sufficient if maintained for the proper period. In both these instances if fixation is inadequate, allowing even the slightest movement of the fragments one on the other, the process of bone repair dependent in turn on the repair of the circulatory damage is interfered with. Nature's efforts become exhausted and fibrous union results. With this clinical experience it is not strange that surgeons have turned to internal fixation as a more reliable method.

INTERPOSITION OF CAPSULE

Interposition of capsule is regarded by many writers as one of the important factors in the production of nonunion. Referring again to the high Schanz osteotomy for nonunion, it will be recalled that late union occurred in about 50 per cent after proved nonunion. If the capsule, as Schmorl found, is interposed in 75 per cent, it is more than likely that the capsule was interposed in at least some of the 50 per cent of cases

in which bony union had been obtained after osteotomy. In other words, it would appear that late union can occur in spite of interposition of the capsule if proper mechanical conditions are provided and the shearing force is eliminated. The observation of Sven Johansson of x-ray evidence of beginning osseous union three months after internal fixation by means of a Smith-Petersen nail in a case of nonunion of fourteen months' standing may also be taken as supporting the view that an insufficient blood supply was not the explanation of failure in the first attempt, since the circulation proved adequate when proper fixation was established.

Can union occur in spite of interposed capsule? In order to test the importance of interposed capsule as a factor in nonunion, the following procedure was carried out on dogs. The femoral neck was cut through with a chisel, and a flap of capsule was turned into the fracture line, completely covering this. The flap was held in place with silk sutures. The hips were then spiked with three knitting needle spikes and the wound was closed. An effort was made to cut the neck off squarely and cleanly. In four the fracture was subcapital and in five transcervical. No external fixation of any kind was used. The operation was unilateral in seven dogs and bilateral in one, a total of nine hips in eight dogs (fig 14).

OPERATION

A straight skin incision 10 cm long is made, centering over the hip joint. Subcutaneous fat is divided and towels are applied to exclude the skin. Division of fascia by incision at right angles to the skin incision exposes the muscles overlying the joint. The biceps femoris which partially overlies the posterior portion of the trochanter is retracted backward. Muscle insertions overlying the trochanter are detached and reflected upward, exposing the capsule. The capsule is now thoroughly freed, and a large square flap is cut corresponding to the outer half of the capsule. This flap is left attached below while the upper margin of the flap is cut close to the acetabular margin. Three sutures are now placed close to

Fig 11—Dupuytren's method of securing traction in case of fracture of the neck of the femur. Two bed sheets placed over thighs and legs respectively as indicated by arrows in the diagram and fastened to the frame of the bed serve to maintain proper position.

the upper margin of the flap, one in each corner and one in the middle to facilitate secure interposition later. The ligamentum teres is not disturbed. With a large bone hook passed around the neck to steady the bone, the neck is now cut through with a chisel. A few black threads are now woven into the capsule to identify this structure, if possible, in later pathologic study. The capsule is now interposed, the silk stitches previously placed being carried with a sharp aneurysm needle for attachment to the medial portions of the capsule. The fracture is now reduced the fragments being held in position during the

introduction of the three knitting needle spikes. The spiking is facilitated by partially drilling the trochanter and distal portion of the neck at the same time tending to avoid displacement of the fragments during the spiking procedure. The muscles are now reattached to the trochanter. The fascia is closed with interrupted catgut, the skin with interrupted silk. The wound is dressed with a single layer of gauze 1 inch wide and the length of the wound held in place with collodion. The stitches are not removed. They work out in from six to eight weeks. No fixation of any kind is used.

All the animals were adult and weighed approximately 35 pounds (16 Kg). Dog 3 died four days after operation, apparently from the effects of previous experimental work having no relation to the present problem. Dog 6 died of wound infection eight days after operation. Dog 5 showed definite nonunion with marked displacement upward of the trochanter. In this case two Kirschner wires were used for the internal fixation rather than the heavier knitting needles with the result that the wires broke and became displaced. This case must therefore be eliminated on the basis of inadequate fixation. In a sense, this dog did not die in vain, as the specimen may serve as evidence that non union in dogs can occur.

Eliminating three hips for reasons noted in the preceding paragraph leaves six hips for consideration. In one instance, the left hip of dog 4 union was only fairly firm because the animal was killed thirty-five days after operation on this hip. In the five other hips in which the dogs were allowed to live from four to ten months after operation union was firm in every instance. As to postoperative data it may be said that weight bearing in walking as well as in running was resumed in from eight to ten weeks, sometimes with scarcely a perceptible limp.

As to pathologic changes, it was noted that in dog 1 in the right hip there was partial luxation upward of the head with marked thickening of the upper acetabular margin the lower

Fig 12—Dry femur showing surface of neck. Note the many large foramina.

half of the acetabulum being filled with a fibrocartilaginous mass. The capsule at the site of defect showed enormous thickening evidently resulting from the need of support of the head to prevent further upward luxation. There was dense fibrous ankylosis at the hip joint but in spite of this the dog bore weight on the leg in walking and in running with but a slight limp. In dog 2 there were no noteworthy pathologic changes. The cartilage of the head and acetabulum appeared normal. In dog 4 in the right hip there was noted a mild inflammatory reaction in the acetabular fossa, evidently the result of

irritation produced by the projection of one of the nails about 1 mm beyond the cartilage of the head. In dog 4 in the left hip the trochanteric bursa showed slight increase in fluid with some fibrin and granulation tissue in the floor, the result of irritation of the ends of the spikes. There was a thin pannus covering about one fourth of the femoral head, otherwise the cartilage was normal. The fundus of the acetab-

ulum showed deep, red granulation tissue. The specimen obtained from dog 5, the right hip, is especially interesting because it is the only case of nonunion. The head was forced frozen into the acetabulum and rotated outward. The trochanter had ridden up so that the neck rubbed against the femoral shaft just below the fracture site, producing highly polished surfaces on both neck and shaft. Specimens from dogs 7 the right hip and 8 the right hip, showed practically normal cartilage of the head and acetabulum. In none of the dogs was a defect noted in the capsule as the result of interposition of the flap. The repair was by fibrous tissue in several instances thicker than the normal capsule.

SUMMARY

It may be stated that in the five cases in which reduction and spike fixation were satisfactory and of sufficient duration firm bony union resulted. In one union was fairly firm with every

indication that firm union would have resulted had sufficient time been allowed. While "dog is dog and man is man and never the twain shall meet," the conclusion seems justified that union can occur in spite of interposition of capsule and that if the circulatory conditions in dog and man are at all comparable repair of the circulatory damage on which healing ultimately depends is possible provided fixation eliminating the shearing force is adequate.

Within recent years aseptic necrosis has been recognized as a factor of very considerable significance in the problem of the fractured neck. No statistics were available to indicate the frequency of the condition. My impression as well as that of colleagues with whom the subject was discussed is that it is much less frequent in (1) impacted fractures and (2) in those cases in which reduction and internal fixation are satisfactory than in nonimpacted fractures treated by conservative methods. If for the sake of argument these assumptions are granted one may speculate on the causes of this difference in incidence. The necrosis, of course, is due to lack of circulation in the head fragment. In the impacted fracture the circulation is much less damaged and fixation is efficient allowing uninterrupted progress in repair. One must think of the mitral repair process in terms of fine capillary shoots penetrating the "bildungs-gewebe," attempting to bridge the gap. The smaller the gap and the more rigid the fixation, the more rapid the repair. In the impacted fracture these conditions are met perfectly. The gap is microscopic rather than macroscopic, and fixation is perfect.

In the nonimpacted cases treated with conservative means the circulatory damage incidental to tears of the synovial membrane and perhaps capsular inclusion is great and the processes of repair of vessel damage are constantly interfered with by movement of greater or lesser extent permitted in spite of careful application of the plaster cast. In the nonimpacted fracture treated by adequate internal fixation, movement is effectually eliminated and repair proceeds undisturbed. The cause

Fig 13—Dry femur. Note the absence of foramina in the fossa.

of the relative frequency of aseptic necrosis in the non-impacted fracture treated conservatively must therefore be placed squarely at the door of inadequate fixation, interfering with circulatory repair. In this connection attention should be called to the work of Carey,²⁸ who measured the stress on the femur during contraction of the thigh muscles produced by the electric current. He removed a 2 inch (5 cm.) section from the middle of the shaft of the femur, replacing this with a hydraulic gage firmly secured by peg extensions into the open medullary canal of the upper and lower fragments. The force of the muscular contraction in the sense of stress on the bone was then readily measurable. His figures are astonishingly high reaching a maximum of more than ten times the body weight of the entire animal. No analogous measurements are available for the neck of the femur but because of the shaft neck angle it is readily seen that contraction of the powerful pelfemoral muscles must result in a tremendous shearing force rather than in pure stress acting in a direction perpendicular to the cross section of the neck. Contraction of these muscles therefore even if the patient is in a large double spica may very well result in a slight shearing motion of the fracture surfaces, one on the other. This no doubt explains the occasional gradual upward riding of the trochanter due to yielding of the immature callus observed even before weight bearing, and sometimes indeed while the patient is still in the cast. In the fracture with satisfactory internal fixation, on the other hand muscular contraction can result only in intermittent pressure in the direction of the longitudinal axis of the neck—pure stress devoid of shearing factor and therefore in stimulation of bone formation.

One point with reference to aseptic necrosis should be cleared up. Reported changes in femoral heads coming on years after fracture when until then no increased density of the head was noted as compared to the rest of the bone must be classified as something other than aseptic necrosis. Just as in osteomyelitis one expects to recognize a sequestrum within a period of three or four months because of the retention of the calcium salts in the fragment deprived of circulation and the carrying off of the lime salts in the living bone, so one should be able to recognize necrosis of the head fragment when it exists, within a reasonable period of time. It is inconceivable that the circulation should be competent for months or years and then fail with resulting necrosis. To me it seems that some of the cases in question must be classified as osteo-arthritis, the changes undoubtedly coming on more rapidly because of the joint damage sustained at the time of injury.

The importance of early activity as a factor promoting union is probably very considerable. It is being stressed more and more in the treatment of fractures in general. It is believed that no one will question the wisdom of early movement at neighboring joints so long as the fragments themselves remain securely fixed. In fracture of the ribs, where motion is uninterrupted because of respiratory movements and where fixation due to the splinting action of the adjacent ribs is efficient fractures heal promptly and nonunion is probably unknown. Clinical evidence of the low ebb of metabolism during inactivity is furnished by the fact that encasement of a child's leg in plaster will cause sufficient bone atrophy within six weeks to allow manual

breaking with but little difficulty. Clark and Swenson²⁹ in studying the circulation in the rabbit's ear have demonstrated on the moving picture film that gentle stroking of the ear will transform narrow, sluggish capillary streams into what looked like raging torrents under the microscope. Since massage is but a poor substitute for muscular activity, the inference is no doubt correct that the blood supply during activity is vastly increased over that in a state of rest. In the impacted fracture and in the spiked fracture one has assurance of secure fixation so that early, in fact immediate, motion within reasonable limits is not only permissible but indicated. Waldenström,³⁰ an advocate of spiking rather than plaster fixation suggests that early motion is conducive to improvement of the circulation through the vessels of the ligamentum teres the alternating stretching and relaxation of the ligament assisting in pumping the blood along its course. Certainly retention for months in plaster with the ligamentum teres stretched taut and compressed, as it must

Fig. 14—Roentgen appearance of pelvis and hips of dog 4 after fracture of the neck of the right femur. Interposition of flap of capsule reduction and spiking. Firm union resulted in spite of the interposed capsule.

be in the widely abducted and extended position, is not compatible with abundant blood supply. Indeed, thrombosis of the vessels under such conditions would probably be a frequent finding if pathologic evidence were available.

While encouraging reports of internal fixation are at hand from many authors each developing his own technique not enough time has elapsed to permit one to speak of end results. It appears likely, however, that end results will be reached earlier in those cases in which internal rather than external fixation is used, since conditions established by internal fixation are more or less comparable to those obtaining in the impacted cases. Complications and mishaps may be expected in any new procedure, and indeed many have been reported, but each such incident has been a lesson often pointing the way to avoidance of danger. It is to be hoped that out of the many procedures all differing somewhat in technical details some method or methods

more or less generally applicable will be developed so that in the hands of skilful surgeons in well equipped hospitals the percentage of success will be materially increased

It is recognized that no one method of reduction will fit all cases, also that not all cases properly reduced and properly spiked will go on to solid union. It is believed however that there is sufficient evidence, clinical and experimental that internal fixation has decided advantages over external fixation and that present day conventional methods, while representing a distinct advance as compared with earlier methods will give way to more precise and more certain procedures

In the foregoing an attempt has been made further to rationalize first the method of reduction of fractures of the neck of the femur by traction in flexion and secondly the method of internal fixation. This attempt is based in part on clinical observation and in part on experimental studies on the skeleton and on animals. If this presentation³¹ will serve in some small measure in placing internal fixation on a sound basis and in stimulating continued efforts at perfection and simplification of the technic insuring a wider acceptance its purpose will have been accomplished

THE TREATMENT OF CHRONIC VARICOSE ULCERS

BY MEANS OF ACETYL-BETA-METHYLCHOLINE
CHLORIDE IONTOPHORESIS

LESLIE SAYLOR, M.D.

TOPEKA, KAN.

JOSEPH KOVACS, M.D.

A. WILBUR DURYEE, M.D.

AND

IRVING WRIGHT, M.D.

NEW YORK

Chronic ulcers associated either with varicose veins or with the occlusions following phlebitis of the deep veins constitute one of the most severe and disabling conditions affecting the lower extremities. Despite the numerous forms of treatment including vein injection recommended during the past fifty years certain of these ulcers fail to heal. This is a report of the results of a new method of treatment of these ulcers which appears to be more satisfactory than any hitherto suggested.

The formation of varicose ulcers is now generally accepted as being the result of venous stasis secondary to the dilatation of the veins and weakening of venous valves. This produces an increasing backpressure into the capillary bed, with the development of pressure edema and the waterlogging of the tissues. With the associated anoxemia, impaired nutrition and accumulation of toxic waste products of metabolism the resistance of the tissues to trauma and infection is reduced. Chronic ulceration may then occur, following the slightest bruise, abrasion, infection or even spontaneously. A similar process frequently follows deep

phlebitis. In many instances, both phlebitis and varicose veins play a part in the production of such ulcers. There has been no difference in response to this treatment so that we have not subdivided these groups in this report.

The actual ulceration may begin with a gangrene and separation of the superficial layers of the skin, or pieces of wet dead tissue of varying sizes, representing the entire thickness of the skin may come away from time to time. In certain instances a portion of the external wall of the vein sloughs away with its covering of skin. These ulcers are usually irregular in shape, only the deeper seated lacunar ulcers are round or oval. These ulcers can usually be differentiated from syphilitic ulcers, which are more clearly "punched out." Blood studies should be used nevertheless to clear up this point in each instance. The size varies from that of a pinhead to ulcers of huge size. The largest in our series was 11 by 6 cm. The base of these ulcers is usually covered by a slough with abundant seropurulent discharge present. The surrounding area is most often indurated, edematous and markedly pigmented.

Logically the healing of varicose ulcers should be dependent on an increase in the local circulation and the elimination of local edema and anoxemia with accompanying improvement in the nutrition of the tissues. Many of the previous forms of treatment such as rest and elevation, elastic bandages, rubber sponge pressure bandages "Unna's boot," injection and ligation of veins have been used in an attempt to promote this physiologic state.

Dianow¹ reported in 1930 thirty cases of varicose ulcers treated by acetylcholine (0.1 Gm daily subcutaneously) in addition to the usual treatment of rest in bed and wet dressings or ointments. Except for one failure all (about 97 per cent) healed in six weeks. Of 109 previously treated in the same way without acetylcholine injections 31 per cent failed to heal and forty-nine of the ulcers required more than six weeks to heal.

Because we believed that the local induction of vasodilating drugs might be even more effective in stimulating the circulation and hence in healing the varicose and postphlebitis ulcers we used acetyl-beta-methylcholine chloride² by the method of iontophoresis as first described from this clinic.³ A preliminary report of nine cases successfully healed by this method was included as a part of a broader study presented before the Section on Pharmacology and Therapeutics of the American Medical Association in June 1935.⁴ These patients had had their ulcers for from seven months to thirty-seven years, without relief from any previously used treatment.

In this paper we present the results of the treatment of the first twenty-six consecutive cases of varicose and postphlebitis ulcers that have come under our care since we began this form of treatment. No selection of cases was undertaken. We would stress the following conditions of our experiments:

1 With three exceptions our patients had been through a control period ranging from one to thirty-seven years during which time all recognized forms of

treatment for this condition had been tried on one or more of them without success

2 During our period of treatment, no patients were hospitalized or put to bed. On the contrary, all were urged to continue their daily occupations, which included washing, ironing, chopping wood, cooking, and selling real estate

Fig 1 (case 14)—S. L. a man aged 30, duration of ulcer four and one-half years, size 1.25 by 0.75 cm, duration of treatment three weeks, number of treatments twelve. Appearance of ulcer July 26, 1935

3 No other form of treatment was used. (A plain petrolatum dressing was permitted during the early stages of the treatment, if it made the patient more comfortable.)

4 No patient received injections for varicose veins during the course of this iontophoresis treatment. After the ulcers had healed, we had the veins injected, when indicated.

The technic of this form of treatment, together with descriptions of local and general reactions, has been described previously by us.⁵ We summarize this material here only briefly.

TECHNIC

A standard 0.5 per cent solution of acetyl-beta-methyl-choline chloride is used. Reinforced asbestos paper is saturated with the 0.5 per cent solution of the drug and wrapped around the foot and leg as high as the knee. The ulcerated area is not covered during treatment until a firm scab has formed over it. After this has occurred, the application may be made directly over the healed area also. A malleable metal plate is placed over the wet asbestos paper and connected to the positive pole of a galvanic machine. The metal plates are never applied over the ulcerated area. A large, regular moist pad electrode is used as a dispersive electrode. This is placed under the back and connected with the negative pole. The current is turned on and slowly increased to 20-30 milliamperes. At the end of the

treatment, the current is slowly reduced and turned off. Treatment is given in some cases daily, but generally two to three times weekly for from twenty to thirty minutes.

GENERAL REACTIONS

A moderately severe reaction resulting from this iontophoresis treatment might be characterized by (1) a marked flush extending over the face, chest and upper part of the abdomen, (2) increase in pulse rate, (3) a deeper, slower respiration cycle, (4) a marked drop in blood pressure (which has been so profound on several occasions that it was necessary to terminate the experiment with atropine), (5) marked salivation (in one instance as much as 140 cc of saliva was collected in twenty minutes), (6) marked lacrimation, (7) profuse diaphoresis, (8) increased intestinal peristalsis with abdominal griping and occasional immediate defecation, (9) occasional substernal pressure, (10) diuresis, in certain individuals, to a varying degree, (11) changes in the electrocardiogram resulting in temporary inversion of the T waves in one or more leads, (12) slight cyanosis at the tips of the extremities, with a drop in surface temperature, which usually rises above the original level in from one to six hours. If desired, immediate cessation of effects may be produced by the injection of atropine, one one-hundredth grain (0.00065 Gm.) subcutaneously.

These systemic reactions constitute an exact duplication of the reactions following the subcutaneous or

Fig 2 (case 14)—Appearance Aug 23, 1935. Ulcer healed, only scaling and pigmentation remain.

intravenous administration of the same drug but are more certain, more prolonged and more easily controlled. They are rarely noted with iontophoresis, except in a mild form.

LOCAL REACTIONS

In addition, there is a characteristic local reaction, directly under the site of the application of the drug. This consists of (1) a feeling of prickling followed

⁵ Kovacs (footnotes 3 and 4)

by warmth during the treatment (2) the appearance of goose-flesh immediately after removal of the asbestos paper (3) a local blush of the skin (4) sweating of the skin, which may continue from six to eight hours, (5) an elevation in surface temperature, during treatment followed by a drop during profuse sweating

Fig 3 (case 17)—U. H. a woman aged 63 duration of ulcer two years size 5.5 by 8 cm duration of treatment twenty weeks number of treatments 100 Appearance of ulcer April 10 1935

(with accompanying evaporation) and a rise above the former level in from one-half to five hours

Neither the general nor the local effects noted can be produced with the use of saline iontophoresis or by the galvanic current alone. Likewise they cannot be produced by merely soaking the area in the solution or by using an ointment containing up to 25 per cent of the drug. Acetyl-beta-methylcholine chloride solution plus the use of the galvanic current must therefore be responsible for the effects.

Individual variations in reactions are noted as in the use of most drugs. Some individuals who scarcely react to the first treatment show an increasing reaction to subsequent treatments.

RESULTS

Twenty-six patients with varicose ulcers have been treated by acetyl-beta-methylcholine chloride iontophoresis. The age the duration and size of the ulcers the duration and number of treatments and the results in each case are given in the accompanying table. Of the twenty-six patients only three did not have satisfactory results. The histories of these three cases are as follows:

The first case with an unsatisfactory result was that of a woman (patient 3) with a post-partum phlebitis and varicose ulcer of eight year duration. She had been bedridden for seven months before we started treatment. The ulcer was healed after twenty-one treatments but when thyroid extract was given by the family physician in doses up to 4-6 grams

(0.26-0.4 Gm) a day, to help the patient reduce, the ulcer promptly recurred and could not be rehealed. The patient was overweight, although the basal metabolism was normal. We are unable to state definitely the cause of the recurrence this time.

The second patient was S. E. (24), a man, aged 31, who had two large varicose ulcers of four years' duration on the right leg. One of these was a punched-out ulcer at the middle of the calf, 2.5 cm in diameter, surrounded by a discolored, brawny, scaly, edematous area, 1.2 by 8 cm in size, in which several small (pinhead sized) ulcers were present. These ulcers healed after twenty-four treatments and the surrounding area was much improved. The other ulcer was located over the internal malleolus. This was 4.5 by 2.25 cm in size, punched out, and surrounded by an inflamed, edematous indurated area of 10 by 5 cm. This ulcer showed no improvement after forty-two treatments. This patient is a cook and must stand on his feet steadily for ten hours a day without rest. Although we have urged all our patients to continue with their daily occupations, because this individual was on his feet more steadily than any other persons in the series, because this ulcer always became more inflamed and painful during the latter part of each day's work, and because we feel that this patient has a complicating deep-vessel phlebitis, it would seem likely, in this one instance that hospitalization would be necessary to insure a reasonable chance of healing the remaining ulcer.

The third patient, B. G. (22), had only four treatments in the course of one week and then had to return to his home, about 150 miles from New York. His family physician is now giving these treatments under our guidance.

COMMENT

The mechanism by which this healing is accomplished is not clear. Two explanations seem possible. The

Fig 4 (case 17)—Appearance Aug 13 1935 ulcer healed only scaling and pigmentation remain

results may be due to either one or to a combination of the two. The production of an increased local circulation may promote a more rapid removal of the waste products and increase local nutrition, thus producing regeneration of the tissues, or secondly the marked local diaphoresis, which may continue for from

four to eight hours after the treatment, may reduce the edema resulting from the hydrostatic pressure, and, by relieving the tissues of this overload of fluid, may permit healing. We realize that it is preferable to close the causative veins as part of the treatment and have recommended injection therapy in suitable cases at the conclusion of the experiment. It is to be expected that, if the etiologic factors are not removed, all ulcers of this type will tend to recur unless treatment is continued. There are however ulcers which do not heal after injections and other cases in which injections are

not to be recommended, as, for example, with diabetes or phlebitis. In these groups this form of treatment should have especial value. We find such patients quite willing to continue to take treatments once a week or every ten days, to prevent the recurrence of their former condition.

When one considers the duration of these ulcers preceding treatment and the fact that the patients were neither put to bed nor given any other form of treatment, the results are encouraging and the method warrants further study and clinical use.

TULAREMIC PNEUMONIA

LEROY H. SLOAN, MD

A. S. FREEDBERG, MD

AND

J. C. EHRLICH, MD

CHICAGO

Tularemia is a relatively newly described disease in medical literature. First described in ground squirrels by McCoy and Chapin¹ in 1912, it was recognized as a disease of man by Francis² in 1922. Since the time of its discovery it has been considered a septicemia and has been recognized clinically in this form.

In 1924 Verbruyck³ first made mention of a pneumonic process specific for this disease in the report of a fatal case with necropsy. Examination of the lung revealed hard, irregular, discrete nodules in the lower lobe of the left lung, and microscopic study showed principally caseation necrosis. The pneumonia with consolidation was not determined clinically, however, and no mention is made of any relationship between these lesions and the disease itself. In 1925 Francis,⁴ in a comprehensive report on tularemia, made no mention of a complicating pneumonia. In a clinicopathologic study Simpson⁵ reported one case of a fulminant tularemic bacteremia with necrotizing nodules in the lungs. In the same year Bardon and Berdez⁶ reported another case with necropsy which revealed a caseous pneumonia very similar, as they remarked, to tuberculosis. Bunker and Smith⁷ reported four similar cases, in one of which *Bacterium tularense* was recovered from the sputum before death. As far as we are able to determine, this is the only report in the literature in which *B. tularense* has been found in the sputum.

The first mention of tularemic pneumonia as a clinical entity appeared in 1931, when three separate reports appeared in the literature. Blackford⁸ suggested that the so-called clinical bronchopneumonias seen in patients suffering from tularemia were probably the result of tularemic pulmonary lesions. In a study of thirteen cases he found six presenting involvement of the lungs, one of which was examined post mortem and showed tularemic abscess cavities in both lungs. Permar and MacLachlan's⁹ patient developed an atypical pneumonia clinically, which at autopsy was found to have been caused by large areas of caseation necrosis in both lungs. They called attention to the grave prognosis associated with such lesions. The pathologic changes were characterized by interstitial and alveolar necrosis apparently due to arteriolar and venous thrombosis. The exudate was described as being chiefly a mononuclear one in the alveoli, and they noted a large

collection of plasma cells in the interstices Sante¹⁰ reported a case of tularemia in which the patient developed a persistent nonproductive cough X-ray examination of the chest revealed an irregular consolidation in one lung The patient slowly recovered and subsequent roentgenograms of the chest were negative The fact that it required months for the chest to clear makes it highly suggestive that this was tularemic pneumonia, as we shall later point out Tureen¹¹ reported a case in which there were pulmonary involvement and an accompanying pleural effusion, the patient recovered, although convalescence was protracted and a thickened pleura was a residue

Gudger's¹² patient died and necropsy revealed a massive pleural effusion accompanied by pulmonary caseation necrosis, no organisms were found in the lung, but culture from the spleen of an inoculated guinea-pig gave a fruitful growth of *B. tularensis* Gudger considered tularemia of the lungs a highly fatal disease and mentioned Tureen's¹¹ report of tularemic pneumonia with recovery as being the only one in the literature up to that time, although Sante's case also seems to fall into this group Gundry and Warner¹³ mention pulmonary lesions as a definite component of tularemia and report one case with necropsy Blackford¹⁴ insisted that pleuropulmonary infections were frequent in patients who recovered Archer, Blackford and Wissler,¹⁵ in an x-ray study pointed out that the diagnosis could not be made by this means alone Kavanaugh,¹⁶ in a review of 123 cases, found six with pleurisy, three with pleural effusions, and one with pneumothorax, the first mention of this complication in the literature In his case it was associated with a fatal outcome Bernstein,¹⁷ in an excellent review of the literature to date, summarizes the twenty-one

recorded necropsies, two of which were unsatisfactory or incomplete as far as examination of the lungs was concerned Of the remaining nineteen, sixteen had pulmonary disease consisting chiefly of caseation necrosis

From what has been said, it seems obvious that tularemia may involve the lungs with a frequency that makes it not at all uncommon Because of the fact

Fig 1—Area of opacity in middle third of right lung Dec 5 1935

that it is generally regarded as a highly fatal disease it occurred to us that report of a case with recovery was indicated

REPORT OF CASE

First Admission—P M., a white man, aged 47, a laborer, born in Italy and residing in the United States for the past twenty-five years, was admitted to the medical service of one of us (L H S) in the Cook County Hospital, Nov 25, 1935, complaining of headache, cough, and chills and fever for one week He stated that his illness was ushered in by a severe chill followed by a high fever and a drenching sweat. He noted severe headache, which became progressively worse, and a cough, which was productive of a thick yellow sputum. There had been no hemoptysis All these symptoms had persisted unabated until the day of admission He had had most of the usual childhood diseases, gonorrhea twenty-five years before and an inguinal herniorrhaphy fifteen years before. His wife had had two spontaneous abortions, but nine children were living and well

Fig 2—Massive effusion in right pleural cavity Jan 16 1936

On admission the temperature was 103 F, the pulse 110 and the respiration rate 24 The lips and nails were faintly cyanotic The pupils reacted well to light and in accommodation, and the eyes were otherwise normal Examination of the throat was negative and there was no cervical adenopathy The heart and lungs showed no abnormalities Aside from a soft spleen, which was palpable one fingerbreadth below the left costal margin, examination of the abdomen revealed nothing of importance. The extremities were essentially normal, and the reflexes were physiologic. It is noteworthy that no cutaneous lesion of any kind was present and no adenopathy. Because of evident sepsis, further inquiry was made and a history obtained of the patient's having skinned a wild rabbit about two weeks before the onset of his illness A tentative diagnosis of tularemia was then made.

The temperature remained elevated, the pulse relatively slow, and the following day the patient complained of severe sticking pain on the anterior surface of the upper portion of the right side of the chest, aggravated by coughing and breathing. Examination of the lungs was again negative, pain continued and four days later dullness tubular breathing, bronchophony and fine moist rales were discovered over the anterior surface of the upper third of the right lung Roentgenograms at this time revealed an area of opacity in the middle third of the right lung extending out from the hilus (fig 1) Four days later, December 9, another roentgenogram showed extension of this process laterally Ten days after admission the temperature became normal by lysis and remained so, although physical and x-ray signs of pulmonary consolidation persisted

A blood count at the time of admission showed 4,500,000 red blood cells, 85 per cent hemoglobin (Tallqvist) and 8,400 white cells, with a differential count of 70 per cent polymorphonuclear leukocytes, 24 per cent lymphocytes, 5 per cent large mononuclears and 1 per cent eosinophils Repeated urinalyses were negative The blood culture was negative on two occasions, as were serum agglutination tests for typhoid and the melitensis porine and bovine strains of *Brucella* The blood Wassermann reaction was negative and repeated stool examinations and cultures revealed nothing unusual Examination of the sputum showed many mixed nonspecific organisms Agglutination for *B. tularensis* was positive 1:160 November 25, 1:640 December 3 and 1:640 December 13

December 19 the patient was discharged with the diagnosis of tularemic pneumonia unresolved X-ray examination at this time still showed considerable density in the region of the right hilus

Second Admission—Jan 15 1936 the patient was readmitted During the interim he had been complaining of dull pain in the right side of the chest associated with some dyspnea For three days prior to this admission he had been coughing a good deal

and had been expectorating about one cupful of thick yellow sputum daily. Physical examination at this time revealed diminished expansion of the right lung, and flatness over the right side of the chest posteriorly from the level of the fifth thoracic vertebra down. Tactile fremitus, breath sounds and voice sounds were totally absent over this area. X-ray examination at this time demonstrated a massive effusion in the right pleural cavity with evidence of slight pneumothorax (fig 2).

Thoracentesis yielded 200 cc of a slightly clouded amber fluid. Stained smears revealed no organisms and a predominance of lymphocytes. Agglutination tests on the fluid for *B. tularensis* were positive 1:512. Serial roentgenograms demonstrated progressively decreasing amounts of fluid in the pleural cavity accompanied by an increased amount of air, and marked thickening of the pleura. Repeated sputum examinations were negative for tubercle bacilli. Cultures of the fluid revealed nothing, nor did inoculation into a guinea-pig. Further agglutination tests for *B. tularensis* on the blood and pleural fluid were increasingly positive up to 1:2,880. Eight days after admission, while bending over, the patient had a violent coughing spell and expectorated about 4 ounces (120 cc) of a thin yellow fluid. Increased cough and expectoration continued for about ten days, during which roentgenograms revealed extensive hydropneumothorax with 80 per cent collapse of the lung (fig 3). A bronchial fistula was suspected. February 18 the patient left the hospital with diminished cough and expectoration and a right hydropneumothorax, with about 60 per cent collapse of the lung.

Examination March 5, revealed dullness over the right side of the chest posteriorly with distant breath sounds and no rales. There was hyperresonance anteriorly and a positive coin test was elicited. A roentgenogram showed a 60 per cent pneumothorax and a markedly thickened pleura (fig 4). The patient's clinical condition was good.

The final diagnosis was tularemia with pneumonia complicating persistent hydropneumothorax, and chronic pleuritis.

COMMENT

From the reports in the literature, particularly in the light of recent pathologic studies, we are led to believe that tularemic pneumonia is not a rare disease, although it is often unrecognized. While only one

Fig 3—Hydropneumothorax Jan 21 1936

instance of recovery of the organism from the sputum has been recorded⁷ and while an absolute clinical diagnosis is difficult in the absence of this finding, the frequent association of caseous pneumonia with tularemia makes it reasonable to assume that an atypical pneumonia developing in a patient with a clinical history of tularemia, particularly if associated with pleural effusion combined

with a protracted course, and the failure to establish tuberculosis or other specific granulomas as the etiology, is sufficient evidence to establish the clinical diagnosis of tularemic pneumonia. It is noteworthy that, in all the reported cases, as in Sante's,¹⁰ Kavanaugh's¹⁶ and ours, the physical and x-ray signs of pulmonary consolidation do not appear until quite late in the course of the disease and do not disappear until long after apparent clinical recovery, if at all.

The process evidently begins with involvement of the hilus, which then spreads peripherally, making early diagnosis difficult.

The prognosis is generally considered to be very unfavorable but reports of tularemic pneumonia with

recovery, together with the fact that many cases are probably unrecognized, throw some doubt on this conclusion.

With regard to pathogenesis, tularemia is usually associated with an obvious cutaneous lesion which is considered the portal of entry, although Francis¹⁸ and Simpson⁵ have shown that the organism may pass through the unbroken skin, although these cases are usually associated with regional adenopathy. It seems reasonable that in so-called typhoidal or cryptogenic tularemia, in which there is neither an ulcer nor adenopathy, the portal of entry may be other than the skin in some instances, as in the respiratory or gastro-intestinal tracts.¹⁰ In our case, for example, the onset of productive cough shortly following the constitutional symptoms, together with the absence of a cutaneous lesion, may be interpreted as being due to a primary tularemic pneumonia. The absence of physical changes may be explained by the presence of localized hilar involvement.

Fig 4—Pneumothorax and thickened pleura March 5 1936

CONCLUSIONS

1 A case of tularemic pneumonia with recovery was complicated by a spontaneous hydropneumothorax.

2 The late onset, the lobular distribution and the prolonged course are the outstanding clinical manifestations.

3 No effective specific treatment is known, in our patient supportive and palliative measures resulted in recovery.

Clinical Investigation in the "Florid Twenties"—Keeping pace with the spirit of abandon which characterized the florid twenties, clinical investigation ran riot, recognizing no bounds, philosophical, intellectual, technical or financial. With apparently unlimited financial resources the business man's concept of mass production tended to creep into academic medical circles without due appreciation of the differences in the aims of business and of science. Under this spell of enthusiasm it seemed reasonable to expect that with organized groups of investigators, spacious laboratories, endless equipment and technical assistance the mysteries of medical science must bow before the concerted onslaught and bow promptly. Medical students and young graduates without consideration of 'Geist' or other qualifications were urged to enter laboratories. The sobering effect of the economic crash upon industrial and financial structures has had far-reaching repercussions and has been seriously felt in most of the clinics of this country. The problem of curtailment and economy has involved all those interested in clinical investigation and we are now confronted with the inevitable and healthy task of taking account of stock and separating the wheat from the chaff. In other words, we must decide what out of this great orgy of clinical investigation, is most worthy of salvage.—Loeb, Robert F. Comments on Clinical Investigation. *Science* 83: 423 (May 8) 1936.

TUBERCULOSIS OF THE CLAVICLE

REVIEW OF THE LITERATURE AND
REPORT OF A CASEJACOB SIRKIN, M.D.
ANDE. A. BAUMGARTNER, M.D.
NEWARK, N. J.

Tuberculosis of the clavicle has rarely been reported. We have been closely observing such a case in the past year and have made a rather careful search of the cases reported. Recently Macey¹ at the Mayo Clinic briefly reported a case of tuberculosis of the left clavicle and right malar bone, both of which are infrequently seen. Coley² reported a case about forty years ago. We have seen no other American reports. There have been twenty-one cases reported in the French literature that we have seen. Couillard-Labonette³ in 1898 gave a review of the literature in which he stated that LeDentu,⁴ Reverdin⁵ and Thierry⁶ had reported cases

Fig. 1—View of chest.

We have included these cases in our report. Couillard also added three new cases of his own. Connor reviewed the literature and, besides quoting the cases cited by Couillard, made reference to a case reported by Bakardjeff.⁸ This, too, has been included in our report. Connor added one new case. Besides these we have found one case described in the German⁹ literature and one in the Scandinavian¹⁰.

Since so few cases have been reported, we have tabulated those found in the literature since 1882, the date of the discovery of the tubercle bacillus by Koch. In the table we have given the pertinent data concerning the cases.

From the Newark State School.

¹ Macey, H. B. Tuberculosis of the Clavicle and Malar Bone. Proc. Staff Meet., Mayo Clin. 10: 289 (May 8) 1935.² Coley, W. B. Tubercular Osteitis of the Clavicle Simulating Malignant Disease. Operation Recovery. New York M. J. 54: 230 1891.³ Couillard-Labonette, J. M. Contribution à l'étude de la tuberculose de la clavicle et de ses articulations. Fac. de med. et de pharm. de Bordeaux 61: 1898.⁴ LeDentu, Soc. de chir. 1882.⁵ Reverdin, Rev. med. de la Suisse Rom. 1886.⁶ Thierry, Thec. de Paris 1890.⁷ Connor, A. Tuberculose de la clavicle. Gaz. d. hop. Paris 77: 1021 1904.⁸ Bakardjeff, Thec. de Montpellier 1902.⁹ Schaefer, H. Leber das Auftreten von Erweichungsherden in Schienbeinkopf. Chirurg. 2: 1 1930.¹⁰ Huitfeldt, Tuberculosis clavicularum behandlet med resektion og fri benplastik fra ribben. Forh. Kri. Trans. kir. for. 1912 p. 51.

The table lists thirty cases. Eleven of the patients were females, eighteen were males, and the sex of one was not stated. The ages have varied from 10 to 72, the latter case being the one reported by Macey.¹ Twenty-one of the patients were between the ages of 10 and 40, and eleven of these were between 20 and 29.

Fig. 2—Close-up view of right clavicle showing destructive process.

Of these eleven, eight were males. There were four females between the ages of 10 and 19. The ages of two were not given. In twelve patients the left clavicle was involved and in eleven the right, while the one diseased was not specified in seven cases.

Fig. 3—View of pelvis showing sacroiliac joint involvement.

In fifteen cases, including ours, just half of those here tabulated we have considered as definite proof that the lesion was tuberculous. In eight of these cases histologic examination was accepted as proof of the case. In two cases material from the lesion injected in a guinea-pig proved the lesion while in a third this was

used as confirmatory evidence. In two cases x-ray evidence alone was given and accepted, and in three others it was confirmatory to histologic examination or guinea-pig inoculation. Tubercle bacilli were found in the curettings or discharge in two patients and, in our patient along with x-ray examination and guinea-pig inoculation, proved the case.

Eighteen patients were treated by excision or resection of the diseased bone, and in ten patients curetting only was done. In several cases curetting was attempted at first and excision practiced later. One patient refused operation and one, accepted as tuberculous from x-ray evidence only, was treated by rest and sunlight. In twenty-one patients the result was said to be good or the patient said to be cured. The outcome of the treatment

inserted because the tumor fluctuated, and a study of the pus showed many tubercle bacilli. The details were as follows:

REPORT OF CASE

The history is rather incomplete owing to the fact that the patient, being mentally defective, cannot give an accurate story of her previous illnesses. Nothing is known of her family except that her parents were mentally defective. She entered the Newark State School in February 1931. She had chicken-pox, measles and mumps as a child, convulsions were present until the establishment of menstruation, she had given birth to two children uneventfully before admission. A diagnosis of mild hyperthyroidism with exophthalmos had been made. She had frequent colds and attacks of tonsillitis. She was ill from August 1932 to January 1933, with a diagnosis of pulmonary tuberculosis, after which time she resumed her usual duties and, apparently, was recovered.

Cases of Tuberculosis of Clavicle

is not given in seven cases, while in two, both after resection, a sinus persisted. For the case in which operation was not done the outcome is not given.

There were known tuberculous foci besides the clavicle in eleven cases. Other bones or joints were involved in four cases, the knee, spine, frontal bone, malar bone and sacro-iliac joint. There was a breast abscess, probably tuberculous, in one of these. The lungs were apparently diseased in five cases, with pleurisy in two, bronchitis in one and pulmonary tuberculosis in two. The glands of the neck had been involved, as shown by the history in two cases. Two cases presented renal tuberculosis, as proved by the finding of tubercle bacilli in catheterized specimens. Ozenne¹¹ is reported as stating that no other foci of tuberculosis were present in his case, while in eighteen no data are given as to other tuberculous lesions.

We have recently had under our care a young woman with a swelling over the clavicle. A needle was

In January 1935 the patient complained of pain in the right hip while walking. Examination revealed no pain on weight bearing but extreme pain was present on internal rotation and abduction of the thigh. Roentgenograms of the hip at that time revealed nothing remarkable. February 6 the patient complained of dysuria and said that she thought the urine had appeared red at times. Examination of the chest and abdomen was negative, and the right hip was the same as before, there was no tenderness at the costovertebral angles and no edema of the extremities. The blood pressure was 120 systolic, 72 diastolic. A kidney function test was done which showed 52.6 per cent phenolsulfonphthalein excreted in the first hour and 15 per cent excreted in the second hour, for a total of 67.6 per cent with a total of 730 cc. of urine. A Mosenthal test of voided urine at that time showed specific gravity for the night urine to be 1.015 and the quantity 930 cc. The day urine varied in specific gravity from 1.005 to 1.015, and the total quantity was 620 cc. The reaction of the different specimens of urine was either neutral or alkaline. Albumin was present in quantities from a trace to two plus. No sugar was found. There were pus and epithelial cells present, few bacteria, and no casts. Menstruation apparently had always been irregular. The patient's weight had been stationary at about 105 pounds (47.6 Kg.).

¹¹ Ozenne M. Ostéite tuberculeuse suppurée avec séquestre de la diaphyse de la clavicule. Congrès pour l'étude de la tuberculose. Bull. méd. 12:845 1898.

Illness—The patient complained of swelling, May 17, with pain and extreme tenderness, at the junction of the sternum and the right clavicle. She stated that there had been no accident or injury.

The patient had a mongoloid appearance, vision in the left eye was impaired. There was an external strabismus of the left eye. The thyroid was slightly enlarged. The tonsils were small and not infected, and the teeth were in good condition. Abdominal striae were present. The heart, lungs and abdominal organs showed no abnormalities on physical examination. Deep reflexes were exaggerated, no pathologic reflexes were present. No lymph glands were palpable in the neck or axillae, but several small ones were found in the inguinal regions. There was no pain in the region of the hips or pelvis on palpation or manipulation. A pelvic examination showed a second degree retroversion, and the right tube contained several small nodules. The left tube was not remarkable. The area at the junction of the right clavicle and the sternum was slightly swollen and quite tender. No redness was present. On pressure a snap could be felt and the protuberance receded slightly. A tight bandage of orthopedic felt was applied and the swelling receded considerably.

The blood pressure was 120 systolic, 72 diastolic and has remained so since. The Wassermann reaction of the blood was negative. The basal metabolism was +2 per cent.

The patient felt much better and on June 5 the swelling was entirely gone and there was no pain. About ten days later the swelling and tenderness again appeared and the same treatment was instituted. There again appeared to be an improvement, but this was not permanent. Finally on two separate occasions greenish pus was obtained by means of a needle (done under aseptic conditions) which revealed many acid-fast bacilli. Inoculation of guinea-pigs each time culminated in their death from tuberculous lesions in the lungs and other organs, with demonstration of numerous tubercle bacilli in these tissues. A few weeks later the area broke down and a sinus resulted. The blood counts at this time ranged from 5,300 to 7,400 leukocytes, with 75 per cent neutrophils, otherwise the count was essentially normal.

Following this, roentgenograms of the chest and pelvic regions were taken by Dr. L. W. Oehlbeck of Clifton Springs, N. Y., who reported: "The fluoroscopic study of the chest shows an elevated left diaphragm, which shows a marked limitation in excursion. Both diaphragms are sharply outlined and the right apparently shows fairly good movement. From the films it is also apparent that there is pleural thickening at the left apex. The hilus shadow on this side is rather heavy and it is possible that there are small calcified areas present. On the right side the apex is clear, but there is a fair area of increased density noted at the infraclavicular area. There is a fair sized defect noted on the exterior surface of the inner end of the right clavicle. The sternal end of the right clavicle appears irregular in outline as compared with the left. There are no changes present to suggest new bone formation."

Conclusions—There is evidence of old tuberculosis on the left with pleural thickening and osteomyelitis of the inner end of the right clavicle. While it is possible that the area of increased density in the right infraclavicular area could be caused by increased thickness of the overlying soft tissue, it would seem well to check this area at a near date in the future.

"Destructive process noted in the right sacro-iliac joint, the cartilage has mainly been destroyed, and the lesion as a whole appears destructive in type without proliferative changes."

The possibilities are good for the lesion being a tuberculous one. This, of course, particularly in view of the fact that other tuberculous foci are already established."

The roentgenograms are reproduced herewith.

The patient was given ultraviolet treatments daily, but with negligible improvement. The temperature varied from 97.2 to 99.4 F., most of the time being between 98 and 98.6 F. October 2 the patient was operated on by Dr. C. W. Webb of Newark, N. Y., who found the sternoclavicular joint apparently normal but the cart just adjacent involved. The necrotic area in the clavicle was curetted and it was noted that the area did not extend into the surrounding tissues. A petrolatum gauze pack was inserted. Boric acid ointment dressings were used and the gauze packing gradually was forced out by the underlying granulation tissue. The temperature varied between 98 and

100 F. until on November 1 it rose to 100.2 F., and she was very uncomfortable in the region of the right kidney. However, the temperature again went down to normal limits for several days, but on November 10 she started to have a temperature of 100.8 F. and by November 13 it began varying from 98.6 to 101.6 F. The blood count on December 4 showed 4,900,000 red cells, hemoglobin 85 per cent (Tallqvist), 20,000 leukocytes, 87 per cent neutrophils, 10 per cent lymphocytes, 27 per cent large mononuclears, and 0.3 per cent eosinophils.

Examinations of voided urine showed acid-fast bacilli with many pus and red blood cells. Albumin ranged about two plus. No sugar or casts were found. Ureteral catheterized specimens of urine showed red cells and pus cells in the urine of the right kidney, while the left urine was clear. Blood urea nitrogen examinations varied from 9.0 mg to 13.3 mg per hundred cubic centimeters of blood.

She remained about the same with a slight drop in temperature until November 18, at which time the temperature began to vary between 99 and 102 F. and she again felt uncomfortable in the right kidney region. November 20 she showed variations in temperature from 98.6 to 103.2 F. The next day the temperature rose to 104.2 F. and the pulse, which previously had ranged from 90 to 120, rose to 158. During this period she was given phenobarbital and codeine as necessary for her pains and on November 25 cystoscopic examination was done by Dr. W. C. Eikner of Clifton Springs, N. Y., who reported that the cystoscope was readily inserted. The urine was found to be grossly bloody and extremely purulent. From eight to ten irrigations were necessary before a clear medium could be obtained. The bladder capacity was estimated at around 250 cc. Inspection of the bladder revealed a rather interesting picture. Surrounding the region of the right ureteral orifice a hopeless conglomerate ulcerative lesion was seen, which seemed to extend over the trigon and was confluent with rather heavy ulcerative and inflammatory processes across the fundus of the bladder. Some areas on both lateral walls were less involved and appeared to be only chronically inflamed. The greater portion of the bladder mucosa, however, was extremely red and either ulcerative or preulcerative in type. Much less of the retraction was seen surrounding the left ureteral orifice than that of the right. The right ureteral orifice was never distinctly seen and retraction was evident as from a chronically infected ureter pulling it upward. Clear spurts of urine were seen from the region of the left. The catheter was readily advanced up the left ureter to the pelvis, with no obstruction being met. It was impossible to engage the catheter in the right ureter. Fairly clear urine was obtained from the left, though drops came irregularly. Indigo carmine was then given intravenously and after seven minutes was seen coming faintly from the left and after ten minutes very strongly. At no time was any seen to come from where the right ureteral orifice should be. Observation was extended for approximately seventeen minutes.

December 9 a right nephrectomy was performed by Dr. John C. Carmer of Lyons, N. Y. The kidney was filled with green pus and microscopically showed evidence of tuberculosis. Since that time the patient has been receiving cod liver oil and ultra violet treatments to the whole body daily. The operated area at the clavicle is still draining slightly but is slowly healing as is the nephrectomy incision. The patient feels very much better, and the temperature has been normal for several weeks. The pulse ranges around 85 and the white blood count varies between 6,000 and 7,000, with about 65 per cent neutrophils. Her weight, which dropped to 85 pounds (38.6 Kg.) at the time of the nephrectomy, has risen to 94 pounds (42.6 Kg.). A guinea-pig, injected with bladder urine seven weeks ago, is gaining weight. The urine is clear, has contained one plus albumin or less, and has contained red cells and white blood cells microscopically. Pelvic examination at present shows no nodules in the right tube. There are no symptoms or signs that show evidence of sacro-iliac disease at present.

At present (June 10, 1936) the patient weighs 108 pounds (49 Kg.) and is up and about. The area at the clavicle has completely healed and the area at the nephrectomy incision has almost healed. The latest urine report shows no red cells, a few pus cells and a trace of albumin, which is an improvement over the previous urinalysis. The last guinea-pig inoculated with the patient's urine was released after nine weeks as not infected with tuberculosis.

COMMENT

Tuberculosis of the clavicle apparently occurs quite infrequently. The older surgeons saw occasional cases of necrosis of the clavicle, these were called syphilis, tuberculosis or cancer. In a review of the literature since 1882 we have found fourteen papers dealing with twenty-five cases of this disease, and in these references were made to four other cases which, with the one we describe, make thirty cases. Age appears to be an important factor, as most of these patients were between 10 and 40 years of age, ten of them between 10 and 20 and only four more than 50 years of age. Sex apparently has little influence, since the disease is about equally frequent in the two sexes. There is no apparent predilection for either clavicle. Some writers have divided the disease according to the part of the bone involved. It would seem that this is not necessary. The question in a few of the reported cases was whether the sternoclavicular joint or the clavicle was the site of the disease. The cases here reported are those showing tuberculosis of the shaft of the clavicle. In our patient it was a question at first as to the joint involvement, but operation showed the joint surfaces normal and the disease in the clavicle. We believe that it was diaphyseal in origin, but in late stages it is difficult or impossible to say that the epiphyses were not involved first.

It is claimed by some that the only method of treatment is by excision. Certainly in some cases curetting appears to have been sufficient for a cure. However, also in some cases curettage has had to be repeated because of a persistent sinus. In two cases reported as treated by resection, sinuses developed and drained a long time. The important point appears to be the complete removal of the diseased portion of the bone. Certainly it is proved that there is no special handicap in complete removal of the diseased clavicle for, if the periosteum is not destroyed, new bone develops. Bone transplantation has been done successfully.

The question of a primary focus in the clavicle vexes here as in other bone tuberculosis. Though infrequently described, there appears to be no anatomic or pathologic reason why primary clavicle involvement cannot occur. Trauma was associated with several of the cases reported, it was definitely not associated in some. Other foci of tuberculosis are described in eleven cases, involving other bones in four cases, while the lungs, glands of the neck, kidneys and breast were tuberculous in others. Our patient had tuberculosis of a kidney and this has been successfully removed, with recovery of the patient continuing to this time. Another unusual tuberculous involvement in our patient is the sacro-iliac joint as is evidenced by the x-ray examination.

CONCLUSION

A patient developing a tumor over the right clavicle was found to have tuberculosis of the clavicle. Apparently developing later, at least with symptoms occurring after this, the right kidney was involved and removed. X-ray examination showed a lesion diagnosed tuberculosis of the sacro-iliac joint by the roentgenologist. The diseased clavicle was curetted and is now healing. Tubercle bacilli were found in the pus removed by needle from the clavicular tumor and injected into guinea-pigs, which developed the typical lesions.

Twenty-nine cases of tuberculosis of the clavicle described in the literature showed that this disease

occurs in the young adult of either sex and that thorough curetting or excision cures the condition. In one case sunlight, with no other treatment, also apparently effected a cure.

529 Church Street.

CULTURE OF HUMAN BONE MARROW

A SIMPLE METHOD FOR MULTIPLE CULTURES

EDWIN E. OSGOOD, MD

AND

INEZ E. BROWNLEE, BA,

PORTLAND, ORE.

In a preliminary report on the culture of human bone marrow¹ a number of problems were outlined for solution. It is our purpose in this note to report progress on problem 4, "development of improvements in the apparatus and of simplified apparatus for multiple short experiments." The original apparatus duplicates as nearly as possible conditions within the body but is so complex that large numbers of experiments could be carried out only at great expense. The method described here, while not duplicating body conditions so exactly, permits satisfactory growth of marrow and is convenient for growing a large number of cultures at the same time.

The method consists in the use of vials with rubber vaccine caps. The type in which sterile 50 per cent dextrose solution is ordinarily dispensed is most satisfactory, especially those with the vaccine caps on each end. The procedure is as follows:

Sterilize the vials in the autoclave or by boiling and, using aseptic technic, introduce into the vials with a sterile syringe and needle the desired amounts of culture medium. Perform a sternal puncture or remove aseptically part of another culture and introduce this material with a syringe and a 20 to 22 gage needle into as many vials as desired. Aspirate filtered gas mixture of any desired composition into the syringe and introduce a needle through the top of the vaccine cap to permit the air to escape from the vial. Force this gas mixture through the lower cap, bubbling it through the medium until it is equilibrated. Then remove both needles and place the vials in an ordinary 37.5 C. incubator or water bath. To withdraw the culture for examination, simply mix thoroughly by shaking and aspirate with a sterile syringe and needle. To change the medium,² allow the culture to settle or centrifuge³ and introduce a needle through the bottom vaccine cap until the point is just above the level of the cells. Withdraw the medium and in a similar way introduce the desired amount of fresh medium.

By the use of this vaccine vial technic it has been possible to make rapid strides in the study of the effects of variation in the composition of the medium, and cultures showing many mitotic figures are now readily obtained. Its disadvantage is that the composition of the medium and that of the gas mixture are not held constant as they are in the original apparatus. The advantages of this technic are its simplicity, the ease of making transfers, and its adaptability to running a large series of cultures differing in only one factor.

Aided by a grant from Eli Lilly & Co. Indianapolis

¹ Osgood E. E. and Muscovitz B. S., Culture of Human Bone Marrow. Preliminary Report J. A. M. A. 106: 1888 (May 30) 1936.

² It seems possible that with the type of vial with one cap kept in a water bath a continuous gas flow or a steady flow of medium previously equilibrated with the desired gas mixture could be introduced through a long needle and allowed to flow out through a short needle slowly enough not to disturb the cells.

³ This type of vaccine vial will fit in the metal tubes of the size used for 100 cc. centrifuge tubes and so can be centrifuged if for any reason removal of the medium is desired shortly after the cells have been mixed.

Clinical Notes, Suggestions and New Instruments

A SIMPLE AND INEXPENSIVE METHOD OF MAKING LANTERN SLIDES OF SKETCHES AND TYPED MATERIAL

SAMUEL J. LEVIN, M.D. DETROIT

The use of lantern slides showing tables, classifications and sketches, during scientific presentations, lends much to the clarity of a paper and has had an increasing vogue. The following method was worked out to obviate the expense of the photographic method of making such lantern slides.

A sheet of cellophane, the size of a standard lantern slide, is placed between two sheets of heavy carbon paper, the carbon side toward the cellophane. These are then placed between two sheets of thin white paper, folded into an envelope of the same size. The material to appear on the slide is typed in the usual manner, a three-fourths inch blank border being left. A clear carbon copy is thus produced on the cellophane, which is then removed and mounted between two lantern slide cover-slips, the edges being taped with standard lantern slide binding tape.

Free-hand sketches can be made directly on the cellophane with india ink by means of a fine pen-point. Diagrams of apparatus can be traced in the same fashion. The india ink dries rapidly after which the sheet of cellophane can be mounted as described.

One of the chief advantages of this method, aside from the considerable saving involved, is the fact that the images projected on the screen from these slides are much larger than those from lantern slides made by photographic reduction. The amount of material that can be typed on the sheet of cellophane is necessarily limited. This may make it necessary to break up large tables into a number of smaller ones, but the resulting images can be seen even in the rear of large lecture rooms.

SEVERE GASTRIC HEMORRHAGE PRODUCED BY VIOLENT ABDOMINAL MASSAGE

WALTER C. ALVAREZ, M.D., ROCHESTER, MINN.

It is fairly well known that severe exertion involving the abdominal muscles can produce hematemesis in patients with peptic ulcer. I can remember a number of such cases. In one instance a traveling salesman, with a big trunk on the back of his car, was lying on his stomach struggling to jack up a rear wheel when suddenly his mouth filled with blood. That a man can put great shearing strain on the movable parts of the bowel that adjoin fixed ones is shown by the recorded cases in which a man, perhaps standing on a chair with his hands above his head putting up a picture, slipped and, in trying to save himself, contracted the muscles of the anterior abdominal wall and tore the duodenum or the first few inches of jejunum so badly that prompt surgical intervention was necessary.

The case here reported is that of a man, aged 31, who has suffered with pains of duodenal ulcer off and on since he was 11. A while ago he placed himself in the care of an irregular practitioner, who put a large electrode on the lower part of the patient's abdomen and sent through him a strong, rhythmically interrupted current which caused all the abdominal muscles to contract vigorously several times a minute. In a few minutes he began to be greatly distressed and shortly afterward before he could call the man back to the booth to shut off the current he began to vomit such large quantities of blood that he became almost exsanguinated and had to have several transfusions. He never showed any other tendency to bleed in the twenty years in which he has had the ulcer.

Certainly it would appear that vigorous massage of the abdomen is not a good treatment for peptic ulcer. In fact,

From the Division of Medicine, the Mayo Clinic

bending over and contracting the abdominal muscles are to maneuvers so hard on many patients with ulcer that one wonders how a laborer with the disease can ever get well. It is hard enough sometimes for a man with ulcer to stay well when he can sit at a desk all day.

Special Clinical Article

THE BONE MARROW

CLINICAL LECTURE AT KANSAS CITY SESSION

R. H. JAFFÉ, M.D.
CHICAGO

The improvement in the technic of biopsies of the bone marrow has added a valuable method to the diagnostic laboratory procedures to which the clinician can resort in the cases in which the examination of the peripheral blood fails to give definite information. The importance of the examination of the bone marrow in vivo becomes evident if one considers the fact that the circulating blood does not always reflect the condition of the bone marrow. Great differences exist sometimes between the cellular content of the blood and that of the bone marrow which may be the source of diagnostic errors. Since the biopsy of the bone marrow is expected to become widely used in clinical medicine, I shall present a brief discussion of the normal bone marrow and of the changes that are observed in some of the important disturbances of blood formation.

THE NORMAL BONE MARROW

In early childhood active, red marrow fills the cavities of all the bones. By the age of 7 years, fat cells start to appear between the cells of blood formation, and with progressing age the active marrow gradually recedes from the distal portions of the skeleton toward the trunk. Its place is taken by an adipose tissue that is somewhat different from the adipose tissue in other locations. Thus its iodine number is different and it contains more cholesterol esters than the other fat deposits of the body. In the adult, the active red marrow is confined to the flat and short bones and to the proximal portions of the humerus and femur (Neumann,¹ Hedinger,² Askanazy,³ Piney,⁴ Turnbull⁵). In the phalanges of the fingers and the toes the bone marrow is rich in connective tissue fibers.

The weight of the bone marrow amounts to from 34 to 59 per cent of the body weight⁶ and there are five ninths of a gram of marrow to one gram of blood. Approximately half of the bone marrow of the adult individual is in an active state (red marrow) while the other half consists of fat tissue (yellow or adipose marrow). The red marrow, therefore, equals in weight

the liver. In advanced age or in wasting diseases the fat may disappear from the marrow to become replaced by a semiliquid gray and translucent material (gelatinous marrow). In dystrophic and malacic diseases of the bone and in chronic inflammation the bone marrow changes into fibrillar connective tissue (fibrous marrow).

The fat tissue of the bone marrow is in a very labile state.⁷ When the demand for new blood cells rises above the normal level new areas of blood formation are quickly formed and the active marrow expands in a centrifugal direction toward the distal parts of the long bones. The small islands of red marrow in the proximal portions of the humerus and femur enlarge and fuse together, and foci of active marrow, which are located about dilated blood capillaries, appear in the midst of the fat tissue. An excessive demand for blood cells may call for a widening of the bone marrow spaces, which is accomplished by the resorption of the bony trabeculae that cross the marrow cavities and eventually also by the resorption of the inner layer of the cortical bone.

Microscopically the red marrow consists of a cellular reticulum the meshes of which are filled with the precursors of the cells of the circulating blood. This cellular reticulum is anchored to the endosteum that covers the inner surfaces of the bone. It forms also the lining of the sinusoidal blood spaces into which the mature blood cells are discharged and which connect the terminal branches of the arteries with the veins. In addition to the sinusoids, in which the blood is circulating very slowly, there are fine capillaries, which are usually closed to the circulation. I believe that all the cells of the bone marrow are derived from a common parental cell, which breaks loose from the cellular reticulum and drops off into the spaces between the branched and anastomosing reticulum cells. In the case of erythropoiesis the mobilized, undifferentiated cell, which has been called the hemocytoblast, develops into a large cell with a deeply basophilic cytoplasm and a round nucleus that contains a fine and dense chromatin net (the erythrogonia). In succeeding generations the cells decrease in size, the chromatin arranges itself in the form of coarse clumps, and in the cytoplasm hemoglobin appears, which causes the cytoplasm to become first amphophilic (polychromatic) and later acidophilic (orthochromatic). Approaching maturity the nucleus shrinks to a small, deeply stained clump, which is finally expelled, and the cell is ready to start on its trip through the body. Normally the very immature and deeply basophilic forerunners of the red blood cells are scanty, and the bulk of the erythropoietic tissue is composed of the smaller cell forms with the different degrees of hemoglobinization of the cytoplasm (erythroblasts and normoblasts). According to Sabin,⁷ Doan⁸ and Peabody⁹ the red cells ripen in the closed capillaries. The anoxemia in these closed capillaries is said to favor the multiplication and maturation of the red cells. When new red cells are needed, the closed capillaries are opened and the mature erythrocytes are discharged into the circulating blood.

The granulated cells are derived from an intermediate, nongranulated and basophilic cell (the myeloblast), which, according to my opinion, is distinctly different from the erythrogonia. Maturation is accomplished by

the formation of granules in the cytoplasm, by a decrease of the basophilia of the cytoplasm, and by structural changes of the nucleus which lead to the lobulated nucleus of the mature granulocyte. The granulated cells are endowed with ameboid motility and pass easily through the wall of the sinusoids. The granulopoietic tissue of the normal marrow is made up chiefly of granulated cells with oval, bean and rod shaped nuclei and well differentiated granulation (myelocytes and metamyelocytes). The youngest, nongranulated cells (myeloblasts) and the cells with the earliest, deeply basophilic and coarse granulation (promyelocytes) are scanty.

The megakaryocytes which originate from the same stem cell as the cells of the erythropoietic and granulopoietic series, are attached to the wall of the sinusoids and extend cytoplasmatic processes through the wall into the lumen of the sinusoids. These cytoplasmatic processes, which are cast off into the blood, form the blood platelets.¹⁰ In addition to the cells described, the normal bone marrow contains lymphocytes, monocytes, plasma cells and a few mast cells. The lymphocytes often form small nodules which are located in the proximity of arterial capillaries.

In sections of normal bone marrow, granulopoietic tissue equals or slightly exceeds erythropoietic tissue (Schilling,¹¹ Doan and Zerfas,¹² Dameshek¹³ and others). In smears made from aspirated bone marrow fluid, from 12 to 25 per cent of the nucleated cells belong to the erythropoietic series (Arinkin,¹⁴ Escudero and Varela,¹⁵ Loewinger,¹⁶ Nordenson,¹⁷ Segerdahl,¹⁸ Young and Osgood,¹⁹ Van der Merve,²⁰ Weiner and Kaznelson²¹). Of the granulated cells, from 0.6 to 3 per cent belong to the oxyphilic variety. There is approximately one megakaryocyte to 400 bone marrow cells (Nordenson,¹⁷ Custer and Krumbhaar²²). The monocytes vary between 2 and 7, the lymphocytes between 5 and 15 per cent.

It is evident that considerable variations exist in the cellular composition of the normal bone marrow. In addition to individual factors, age, sex, race, diet and stage of nutrition, the climate and the geographic location play an important role. In high altitudes the erythropoietic tissue will be more active than in the lowlands. Hedinger² refers to the significance of endemic goiter.

In the time allotted to me I shall be able to discuss only one of the functions of the bone marrow, namely,

the formation of the blood cells. It may be mentioned, however, that as an important part of the reticulo-endothelial system the bone marrow shares in all the functions that have been attributed to this system, as for instance the formation of the bile pigment, the production of antibodies and the storage of certain substances which are either foreign to the body or accumulate in the tissue fluids in excessive amounts. Thus in Gaucher's disease and in Niemann-Pick's disease, which, as the recent important studies of Thannhauser²³ have shown, is closely related to the former, the storing capacity of the reticulum cells of the bone marrow may be taxed to a degree that the production of the blood cells is diminished. The bone marrow contributes to the blood proteins, especially the fibrinogen, and produces more prothrombin than the spleen and the liver.

The mechanism that regulates the maturation of the blood cells and their discharge into the circulating blood and is responsible for the fairly constant cellular composition of the blood is still poorly understood. The granulated cells enter the blood in a certain rhythm, which shows small hourly accessions and a larger diurnal tide in the afternoon and at midnight. Chemotaxis and the stimulating effect of degradation products of cells on the homologous cells (Myagow's principle) seem to play an important role. With regard to the erythropoiesis it has been stated that the new formation and mobilization of the erythrocytes is controlled by the oxygen tension of the blood. Hoff,²⁴ Dockhorn,²⁵ and Papilian²⁶ and others suggest a regulation of the activity of the bone marrow through the vegetative nervous system but Naegeli²⁷ points out that the nerve fibers of the bone marrow are restricted to the proximity of the blood vessels. The depressing influence of the spleen on the bone marrow has been often discussed and seems to be borne out by experimental studies as well as by clinical observations. The hormones of the thyroid gland stimulate apparently the bone marrow, and Roger²⁸ suggests that the hormones of the pituitary gland and the gonads may have a similar effect (see also Naegeli²⁷). According to Hubble,²⁹ the hormones of the suprarenal cortex increase the productivity of the erythropoietic and granulopoietic tissue, and the basophilic cells of the anterior lobe of the hypophysis exert a stimulating influence on all the blood forming cells and produce eventually polycythemia vera. This action of the anterior pituitary lobe may be an indirect one through the thyroid and the adrenal. The productivity of the normal bone marrow is tremendous. If one assumes that the average span of life of the erythrocyte is about four weeks, 900 billions of erythrocytes are produced daily by the bone marrow.² Finally it may be emphasized that the formation of the blood cells and the passage of the blood cells into the blood stream are two distinctly separate and independent phenomena.

THE ANEMIAS

In anemia the erythropoietic tissue of the bone marrow may be increased (hyperplastic), diminished (hypoplastic) or exhausted (aplastic), or it may present deviations from the normal mode of maturation with the formation of abnormal red cells (dysplasia). In the active stage of pernicious anemia the dysplasia of the erythropoiesis is the outstanding feature. The red marrow usually replaces most of the fatty marrow, although in some cases a considerable amount of adipose marrow may persist.³⁰ The erythropoietic tissue greatly exceeds the granulopoietic tissue, and the megakaryocytes are few in number and often degenerated. The erythropoietic tissue contains many very immature, large basophilic cells, which are often found in mitotic division, and it is already in this early stage of differentiation that the hemoglobinization of the cytoplasm begins. Owing to this premature hemoglobinization, large cells result the cytoplasm of which is very rich in hemoglobin and the nucleus of which has the dense, reticular structure of the hematogonia (the *novau perle* of the French authors). These cells are the megaloblasts, which were first described by Paul Ehrlich and which are typical of pernicious anemia and certain other forms of hyperchromic macrocytic anemia. Turnbull³¹ emphasizes that much confusion has been caused by the erroneous identification of the megaloblast with the earliest cell forms of the erythropoiesis. The latter are found in many types of severe anemia. The megaloblast of pernicious anemia is a cell which contains hemoglobin and which loses its nucleus by pyknosis and extrusion like the normoblast. The product of the megaloblastic erythropoiesis is rich in hemoglobin, a real functional giant which is doomed to quick destruction, since it is an abnormal cell. The majority of the investigators consider the megaloblast as characteristic of pernicious anemia (Arinkin,³² Becart,³¹ Dameshek,³³ Holmes and Broun,³² Jagic and Klima,³⁴ Loewinger³⁵ Naegeli,²⁷ Peabody,³⁴ Piney,³⁶ Segerdahl,³⁸ Tempka and Braun,³⁶ Turnbull,³¹ Van der Merwe²⁰ and others). Van der Merwe²⁰ recommends examination of the sternal bone marrow for the differential diagnosis of pernicious anemia and carcinoma of the stomach with pernicious-like blood changes. In contrast to the proliferation of the erythrogenias and their abnormal maturation into megalocytes and gigantocytes, erythroblasts and normoblasts are scanty in the bone marrow of cases of pernicious anemia. The granulopoietic tissue which is relatively diminished in quantity presents certain anomalies. Thus the myeloblasts are increased in number and there is a premature lobulation of the nucleus which starts at the time when the granulation is still scanty and young. The lobulation of the nucleus progresses and when the mature leukocyte is formed its nucleus has many more segments than the normal leukocyte (so-called shifting to the right). When the dysplasia of the bone marrow of pernicious anemia

approaches the stage of exhaustion plasma cells become a conspicuous feature.³⁷ Perlebody³⁸ and many others have observed that in pernicious anemia the reticulum cells of the bone marrow become transformed into macrophages which engulf many erythrocytes. This erythrophagocytosis seems to be pronounced only in autopsy material.

The antianemic treatment prompts a reversion of the megaloblastic erythropoiesis to the normoblastic type (Becart,³¹ Dameshek,¹³ Peabody,³⁴ Van der Merwe³⁰). A similar reversion takes place during a spontaneous remission. The megaloblasts disappear, the most immature cell forms decrease in number, and erythroblasts and normoblasts dominate the picture. The red marrow recedes to the trunk. Nordenson¹ states that with liver therapy the return to the normal blood formation requires approximately twelve days. Segerdahl¹⁸ observed, after large doses of liver, a disappearance of the megaloblasts within twenty-four hours and suggests the determination of the disappearing time as a criterion for the potency of an antianemic substance. Under the influence of infectious irritation the dysplastic bone marrow of pernicious anemia may fail to respond to antianemic treatment.³⁹

In the macrocytic anemia of sprue the cytologic picture of the bone marrow is similar to that of pernicious anemia but the megaloblastic transformation is decidedly less marked (Witts, Fairley and Goodhart⁴⁰ Rhoads and Castle,⁴¹ Turnbull⁴). The response to effective treatment is the same as in pernicious anemia. The macrocytic anemia associated with diseases of the liver fails to show the megaloblastic reaction of the bone marrow (Rossier,⁴² McLamos⁴³).

The bone marrow of the patients with hypochromic microcytic anemia is hyperplastic and the erythropoiesis which does not show any obvious morphologic anomalies predominates over the granulopoiesis. Megaloblasts are absent (Dameshek,¹³ Van der Merwe³⁰) but small groups of erythrogonias are found. There are numerous normoblasts and, in severe cases, also many polychromatophilic erythroblasts.¹⁸ It has been suggested that the deficiency in iron may interfere with the final stages of erythrocytic maturation. Under adequate iron therapy the hyperplastic marrow recedes.⁵

Loewinger,¹⁶ Young and Osgood,¹⁹ Dameshek¹³ and Weiner and Kaznelson²¹ describe a great predominance of the nucleated red cells in the bone marrow in cases presenting hemolytic family jaundice. The nucleated red cells vary considerably in size, and macronormoblasts and micronormoblasts are found. After splenectomy the macronormoblasts disappear but the micronormoblasts persist.²¹ According to Jones,⁴⁴ the erythropoiesis in acholuric family jaundice shows a peculiar though nonspecific anomaly which consists of the direct transformation of the reticular cells into normoblasts without the intermediary stages of differ-

entiation. In sickle cell anemia the nucleated red cells of the bone marrow are of normal shape.⁴⁵ In the erythroblastic anemias of infancy and early childhood the bone marrow is extremely hyperplastic, leading to a more or less marked reduction of the bony structures. The marrow is crowded with erythroblasts and there are also many erythrogonias. Normoblasts are often less conspicuous than the earlier forms of erythropoiesis. The granulopoietic tissue which is relatively scanty, may be rich in oxyphilic myelocytes, and the megakaryocytes are numerous.

In typical aplastic anemia the bone marrow fails as a unit (Frank,⁴⁶ Lescher and Hubble,⁴⁷ Middleton and Meyer⁴⁸ and many others). Pure red cell aplasia is very rare. A considerable number of authors have been struck by the fact that in cases which clinically show most of the symptoms of aplastic anemia the bone marrow is found normal or even hyperplastic (see for instance Thompson, Richter and Edsall⁴⁹). These cases, however, usually show some evidences of regeneration in the peripheral blood and should properly be separated as pseudo-aplastic anemia from the true aplastic anemia.⁵⁰ In analogy to the observations of Frank,⁴⁶ Sheard,³⁰ Dameshek,¹³ Young and Osgood¹⁹ and others, I have found in typical cases of aplastic anemia an extreme exhaustion of the bone marrow. Careful search may disclose an occasional small nest of myeloid cells, but the majority of the cells that are found between the fat cells prove to be plasma cells, lymphocytes, monocytes and proliferated histiocytes. There are no apparent differences in the histologic picture of the bone marrow between the cases of idiopathic and symptomatic aplastic anemia. In osteosclerotic anemia the bone marrow changes into connective tissue, which later becomes ossified. The ossification of the marrow cavities may be secondary to an aplasia of the bone marrow, as for instance in the senile osteosclerotic anemia, or it may be due to a congenital anomaly of the bone forming tissue, as in Albers-Schoenberg's marble bone disease.

POLYCYTHEMIA VERA

Vaquez's disease is associated with a hyperplasia of all the elements of the bone marrow (hyperplastic panmyelopathy of Askanazy). Reznikoff, Foot and Bethea⁵¹ have recently advanced the theory that the increase in red cells may be the reaction to a fibrosis of the wall of the capillaries and arterioles of the bone marrow which causes an anoxemia and a compensatory excessive erythropoiesis. Whether this explanation holds true for all cases of polycythemia remains to be shown. It does not take into account that not only the erythropoietic tissue is hyperplastic but also the granulopoietic tissue and the megakaryocytes, and that polycythemia vera shows the tendency to change into myelogenous leukemia. Attempts have also been made to consider polycythemia vera the counterpart of per-

pernicious anemia and to explain it on the basis of an excessive production of the hematopoietic (anti-anemia) substance which is supposed to be formed in the stomach (Morris,⁵² Hitzengerger,⁵³ Barath and Fülöp⁵⁴)

AGRANULOCYTOSIS

Similar to the disturbances of erythropoiesis one can distinguish between hyperplasia, hypoplasia, aplasia and dysplasia of the granulopoietic tissue. Agranulocytosis is one of the most striking examples of the discrepancies that may exist between the conditions present in the peripheral blood and the condition of the bone marrow. Schultz⁵⁵ and after him many authors have described an aplasia of the granulopoietic tissue as characteristic of agranulocytosis and unquestionably in some instances the disappearance of the granulocytes from the circulating blood is due to an exhaustion of the granulopoiesis. In their recent book on agranulocytosis, Sabrazes and Saric⁵⁶ expressly state that the bone marrow of the sternum, vertebral bodies and epiphysis of the long bones is devoid of granulocytic elements. Soon after Schultz's first publication it became, however, apparent that aplasia of the granulopoietic tissue was not the rule in a granulocytosis and that cases occurred in which the bone marrow was either normal or hyperplastic. The combination of a profound neutropenia of the circulating blood with an active multiplication of the progenitors of the neutrophils in the bone marrow induced Fitz Hugh and Comroe⁵⁷ to suggest that the essential disturbance in agranulocytosis might be an arrest of the maturation of the granulocytes. In a subsequent study Fitz Hugh and Comroe⁵⁸ brought forward additional proof for this explanation, which was also greatly strengthened by the careful histologic investigations of Custer⁵⁹ and Darling, Parker and Jackson.⁶⁰ Custer⁵⁹ pointed out that the failure of the proliferating myeloblasts to differentiate into myelocytes and neutrophilic leukocytes might result from the lack of an intrinsic maturation factor. Similar to pernicious anemia in which the erythron is affected, agranulocytosis then would be a dysplastic condition of the granulopoiesis. From the cases of agranulocytosis which I have studied I have obtained the impression that the early cell forms of the granulopoietic series proliferate but that they fail to mature because they degenerate. This degeneration, which may be caused by toxins or which may be an allergic phenomenon, explains, I believe, better the fulminating and so often rapidly fatal course of the disease than a mere maturation arrest. Tissue cultures made from the bone marrow of patients suffering from agranulocytosis may help to decide whether it is a maturation arrest or a degeneration that prevents the

young granulopoietic cells to ripen. In the cases in which the peripheral neutropenia is associated with an active proliferation of healthy, young granulocytes in the bone marrow, a disproportion between the supply and the destruction of the mature granulocytes in the circulating blood may exist, just as in hemolytic anemia the increased erythropoiesis fails to compensate for the destruction of the erythrocytes. The investigators who distinguish sharply between idiopathic and symptomatic agranulocytosis emphasize that the maturation arrest is pathognomonic of the idiopathic form and is not observed in the symptomatic form. The other elements of the bone marrow do not seem to be affected in agranulocytosis. Prolonged agranulocytosis leads to a proliferation of the plasma cells and histiocytes of the bone marrow.

THE LEUKEMIAS

In leukemia the bone marrow is usually very hyperplastic. The microscopic picture of the leukemic bone marrow depends on the type of leukemia, but within the same group considerable individual variations may occur. In chronic myelogenous leukemia there is a diffuse hyperplasia of the bone marrow and I have often observed that the relation between erythropoiesis and granulopoiesis is maintained at the normal level. The granulopoietic tissue is composed mainly of myeloblasts and promyelocytes. The latter are unusually large and their granulation is atypical, irregular and scanty. The myelocytes may mature to fairly normal neutrophilic leukocytes. In cases presenting very high counts of the white blood cells I have frequently found that the neutrophils which are derived from the abnormal myelocytes are small and crippled with a poorly defined granulation, a scanty cytoplasm and an abnormally lobulated nucleus. Thus there is in these cases not only a hyperplasia but also a dysplasia of the granulopoiesis. Some cases of myelogenous leukemia show a predominance of eosinophilic or basophilic myelocytes and leukocytes.

The more rapid the course of the leukemia, the greater is usually also the percentage of the earliest cell forms. In acute myelogenous leukemia the bone marrow is packed with myeloblasts. In many cases of acute leukemia, especially in children, the hemocytoblast excels by far all other cells. The hemocytoblast may show a greater tendency to differentiate in the erythropoietic direction than in the granulopoietic direction. There are cases of acute and of subacute leukemia in which the proliferation of the megakaryocytes and their precursors is the outstanding feature, and other cases in which the bone marrow consists chiefly of immature monocytes. A few cases of leukemia have been described in which the bone marrow is composed of plasma cells.⁶¹

In most of the cases of lymphatic leukemia the bone marrow resembles lymphatic tissue. Granulopoietic and erythropoietic tissue, however, persists in the form of small perivascular islands which, under the influence of complicating infections, may become greatly activated and replace most of the lymphatic tissue. In this connection I mention the atypical cases of lymphatic leukemia in which the proliferation of the lymphatic cells is confined to the bone marrow, and the liver, the spleen and the lymph nodes are not affected (medullary

lymphatic leukemia of Aubertin,⁶² Liotti,⁶³ Fries,⁶⁴ Hirschfeld⁶⁵ and Zanatz⁶⁶)

It is in the typical cases of leukemia in which the blood examination or the clinical picture does not correspond to the classic description that the biopsy of the bone marrow will be found very useful. I refer to the acute aleukemic leukemias, which are often confused with aplastic anemia, thrombocytopenic purpura or septicemia, and to chronic aleukemic myelogenous leukemia, which is frequently diagnosed as morbus Brunt or sepsis lenta. During the past few years I have studied forty-seven cases of acute leukemia seven of which were aleukemic throughout their entire course and nine cases of chronic myelogenous leukemia two of which had never shown a leukemic blood picture. In none of these nine cases was the leukemia recognized during life. The value of a new method can be appreciated if one is familiar with its limitations. There are rare cases of leukemia in which the bone marrow biopsy is disappointing. Long standing myelogenous leukemia, in particular its aleukemic variety may finally lead to an exhaustion of the bone marrow and the marrow becomes replaced by connective tissue or bone (osteosclerotic aleukemic myelosis). In the early stages of very acute cases of leukemia the bone marrow may be hemorrhagic and poor in myeloid cells (Jaffe,⁶⁷ Segerdahl¹⁸)

THROMBOCYTOPENIC PURPURA

According to the current conception the megakaryocytes are the source of the blood platelets, and thrombocytopenic purpura (Werlhof's disease) has therefore often been attributed to an alteration of these cells. Because of the loss of blood from the multiple hemorrhages the bone marrow is hyperplastic. The megakaryocytes are numerous. I have counted from two to four megakaryocytes per hundred bone marrow cells. Many of them are well preserved except that they are smaller than normal and that their fine azurophilic granulation is often missing. This disappearance of the specific granulation of the megakaryocytes has been stressed by Frank⁶⁸ and Schmincke,⁶⁹ and Frank believes that it may be due to a maturation arrest. Frank⁶⁸ and Schmincke⁶⁹ describe also severe degenerative changes which I have not been able to find. It should be remembered that single degenerating megakaryocytes are present in the normal bone marrow. Rohr⁷⁰ refers to a peculiar configuration of the megakaryocytes in thrombocytopenic purpura: the cytoplasmatic protrusions disappear and the cell borders become straight and sharp. After splenectomy the budding of the cytoplasm is said to reappear. From these observations it would seem that thrombocytopenic purpura is due to a dysplasia and not to an exhaustion of the thrombocytopoiesis. Falconer and Morris¹ advise against biopsy of the bone marrow in cases of purpura.

HEMOPHILIA

In a recent publication Custer and Krumbhaar²² describe the appearance of the bone marrow in three cases of hemophilia. They emphasize that the erythropoiesis and granulopoiesis are strictly normal, both being very active, and that the megakaryocytes are distinctly more numerous than normal. The morphology of the megakaryocytes shows no anomalies.

TUMORS OF THE BONE MARROW

It is interesting to note that the plasma cell, which plays only a minor role in normal blood marrow, is the most common source of primary neoplasms of the bone marrow. Of ten myelomas that I have recently studied, eight were composed of plasma cells, one of myelocytes and one of lymphoblasts. In the literature there are also reports on erythroblastic myelomas. Of the other tumors that originate in the bone marrow I mention reticular cell lymphosarcoma, liposarcoma and benign angioma and angiosarcoma.

BONE MARROW BIOPSY

The upper portion of the sternum, at the height of the second or third rib has been found the most suitable place for the removal of samples of the bone marrow. The sternal marrow remains active throughout life, and the anterior cortex of the bone is only from 0.9 to 2 mm thick. The thickness of the sternum amounts to about 1 cm (Van der Merwe²⁰). Two methods have been recommended, one of which consists in the removal of a core of marrow with the aid of a small trephine (Custer,²⁰ Dameshek,¹³ Tuohy and Gillespie¹²) while the other is based on the aspiration of marrow fluid through a modified spinal puncture needle (Amprino and Penati,⁷³ Arinkin¹⁴ Baserga,⁷⁴ Becart,³¹ Henning,⁷⁵ Klima and Rosegger,⁷⁶ Loewinger¹⁶ Reich,⁷⁷ Segerdahl,¹⁸ Van der Merwe,²⁰ Young and Osgood¹⁹). For research and systematic studies the former method is the method of choice, since it permits sectioning of the marrow with preservation of the topographic relations of the cells and also the preparation of smears and imprints. Aspiration biopsy has the advantage of simplicity and does not require the technical skill that is necessary for the first method. With aspiration biopsy one must keep in mind that the aspirated fluid does not give the correct picture of the bone marrow in situ because cells that are still connected with the reticulum are less apt to become mobilized than cells that are free. The inflowing blood will necessarily dilute the aspirated material and it is therefore advisable not to aspirate more than 0.1 or 0.2 cc. After coagulation in a small watch glass the aspirated fluid can be fixed and sectioned like a piece of bone marrow (Amprino and Penati⁷³). In the majority of cases a carefully prepared spread of the marrow fluid will be found sufficient to obtain definite information as to the condition of the bone marrow.

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION FRANKLIN C BING, Secretary

HALE'S PRIDE VEG-ALL

Distributor—Halc-Halsell Company, McAlester, Okla

Manufacturer—The Larsen Company, Green Bay, Wis

Description—Mixture of carrots, potatoes, celery, green beans, cabbage, peas, corn, lima beans, onions, sweet peppers, salt and water prepared by efficient methods for retention in high degree of the natural mineral and vitamin values, the same as the accepted "Larsen's Veg-All" (THE JOURNAL, Aug 12, 1933, p 525)

FORT HAMILTON BRAND PINEAPPLE JUICE

Distributor—The E H Frechtling Company, Hamilton, Ohio

Manufacturer—Hawanan Pineapple Company, Ltd, San Francisco

Description—Canned Hawaiian pineapple juice retaining in high degree the natural vitamin content, the same as Dole Hawaiian Finest Quality Pineapple Juice (Unsweetened) (THE JOURNAL, June 3, 1933, p 1769)

REYNOLDS STURGEON BAY BRAND PITTED RED CHERRIES WATER PACK—WITHOUT ADDED SUGAR

Manufacturer—Reynolds Preserving Company, Sturgeon Bay, Wis

Description—Canned cooked red Wisconsin cherries packed in water without added sugar or salt The same as Cello Red Pitted Cherries Packed in Water Without Added Sugar or Salt (THE JOURNAL, Sept 14, 1935, p 885)

GOLD-PAK BRAND GRAPEFRUIT JUICE

Manufacturer—Ariz-Sweet Grapefruit Growers, Ltd, Peoria, Ariz

Description—Canned Arizona grapefruit juice, retaining in high degree the original vitamin C content The same as Ariz-Sweet Brand Grapefruit Juice, THE JOURNAL, April 25, 1936, page 1474

GRIDLEY (FAST FROZEN) CHOCOLATE ICE CREAM

Manufacturer—Gridley Dairy Company, Inc., Milwaukee.

Description—Pasteurized, homogenized, chocolate flavored ice cream containing cream, evaporated milk, sugar, milk, cocoa, chocolate liquor, egg yolk, gelatin, vanilla extract and salt Contains not less than 13 per cent milk fat. For description of manufacture see THE JOURNAL, Sept 7, 1935, page 801

ADVERTISING LEAFLET "PUBLICATIONS OF THE IRRADIATED EVAPORATED MILK INSTITUTE"

Sponsor—Irradiated Evaporated Milk Institute, Chicago

A leaflet which lists and describes the educational material available from the institute.

RECIPE LEAFLET "BEST OF FRIENDS ON BAKING DAY"

Sponsor—Irradiated Evaporated Milk Institute, Chicago

A leaflet intended for distribution through welfare groups Includes recipes in which irradiated evaporated milk is used

SATURDAY, JULY 11, 1936

THE STRENGTH OF BONE

The several types of connective tissue are not greatly dissimilar when considered from the point of view of qualitative chemical composition. Tendon, cartilage and bone in the laboratory all yield essentially the same kind of compounds. The chemical difference between these tissues lies largely in the relative quantities of the characteristic substances constituting them. From each can be obtained collagen, mucoid and inorganic salts, but even the beginner in histochemistry is aware of the fact that the so-called ash constituents play a far more important part in the make-up of bone than they do in cartilage or tendon. This localization of inorganic salts in bone has long been considered the characteristic chemical feature of this tissue. Although the skeleton of the new-born mammal is more or less cartilaginous, the proportion of ash increases with age, under ordinary conditions of nutrition, until at maturity considerably more than half of the mass of the dry, fat-free bone consists of inorganic material. To add further significance to this reservoir of salts is the fact that almost the entire supply of the indispensable calcium of the body resides in the bones. It is reasonable therefore that, in considerations of the function, pathology and repair of bone, attention is focused primarily on this distinguishing aspect of its composition.

In the light of this emphasis, it is interesting to note in a recent report¹ the conclusion that under certain conditions the strength of bone depends more on the organic part of this tissue than on the degree to which the bone approaches the normal composition as regards the inorganic portion. In this study, groups of young rats were restricted for various periods to experimental rations extremely poor in mineral salts. At the end of this interval the breaking strength of the bone was correlated with the composition and with the measurements of length and two diameters. Although increase in body weight was largely suppressed by the dietary

restriction imposed, there was appreciable increase in length and diameters of the representative bones examined. However, the strength of these bones was subnormal. Other groups of rats similarly treated were realimented with an adequate ration and the same tests made at stated intervals of refeeding. One group stunted for three weeks and refed for six weeks showed a definitely greater breaking strength than a second group stunted for six weeks and refed for twelve weeks. Further examination of the data shows that this difference in strength could not be correlated with the ash content of the respective bones but that where the strength was greater, the measurements of the bone more closely approached those of the normal controls. It was apparent that the early period of restricted nutrition had adversely affected the architecture of the bone, as reflected in the measurements, to a degree somewhat proportional to the duration of the under feeding. Likewise it appears that within limits "the breaking strength of a bone is more closely correlated with the integrity of the organic pattern as reflected in size than with the amount of inorganic matter deposited in the bone."

The studies described deal with dietary adjustments far more extreme than any likely to be encountered in practice. Nevertheless the results point definitely to the importance of serious consideration of the non mineral part of the skeleton in certain situations. These observations will be of particular interest in the fields of orthopedics, surgery and dental pathology, in which not infrequently therapeutic emphasis involving oral administration of calcium salts seems somewhat misplaced.

BCG AS A TUBERCULOSIS PREVENTIVE

There are a number of reasons why the use of the living vaccine known as BCG, twelve years after its first use in France, should still be discussed and debated among those concerned with the prevention and cure of tuberculosis. It has never been conclusively demonstrated that the use of this vaccine is an effective means of preventing human tuberculosis. The reports of studies of its value as an effective vaccine in animals are greatly at variance despite the fact that these studies have been made by excellent investigators. The greatest value of BCG is in cattle but, in view of the variation in reported results, one could scarcely conclude that it is justifiable to use it universally in man. Those who have tried to produce a fixed virus without virulence using a bile medium by the method of Calmette and Guérin have failed to do so. Especially notable in this connection are the studies of A. Stanley Griffith¹ using seven bovine strains and exactly the method of the French scientists over a period of ten years. Yet he failed to alter the virus.

Since 1900 it has been well known that the injection of certain strains of tubercle bacilli raises the resistance

¹ Clarke M. F., Bassin A. L. and Smith A. H. *Am. J. Physiol.* 115: 546 (May) 1936.

¹ Griffith A. S. *Lancet* 1: 303 (Feb. 6) 361 (Feb. 13) 1932.

of certain animals to a later killing dose of virulent tubercle bacilli. But the vaccination of man with living tubercle bacilli had never been seriously proposed until 1922, when Professor Calmette enthusiastically suggested it and French physicians began to practice it. This enthusiasm was not shared by British and American physicians primarily because the determination as to whether it should be used in commerce was in Great Britain in the hands of the Medical Research Council and in the United States in the hands of the National Institute of Health (U. S. Public Health Service) and the Bureau of Animal Industry (Department of Agriculture), which are government agencies. Their conservatism was based on the premise that the ability of the vaccine to justify the claims of the French scientists should be proved by animal tests before employing it wholesale in man.

The enthusiasm with which the French scientists advocated their prophylactic vaccine received a severe blow from the American and British point of view when Prof. Major Greenwood² in England criticized the methods of statistical study that were used by Calmette to prove the value of his vaccine. There is still a great tendency to base conclusions on empirical observations rather than on rigid scientific technique in human epidemiologic studies, in which it is so difficult and so important to provide comparable controls.

The method of administering the vaccine has changed three times in this period. Administration by mouth in the early days of life was first advocated. This apparently is gradually disappearing as a method of election. The next method was administration by subcutaneous injection. This was so frequently followed by "cold abscesses" that this also is gradually giving place to the method of intracutaneous injection. Experiments in animals have shown little value for the oral method as a means of prevention. The subcutaneous method and the intracutaneous method are variable in their results in animals. The intravenous method³ of vaccination has proved to be the most efficacious in cattle, although this also varies within wide limits. The greatest difficulty has been to determine how long the period of increased resistance lasts. This also apparently varies in many instances and is often of short duration, that is, under one year.

Many different cultures of BCG have been sent to the United States in the hands of various persons, laymen and physicians alike. Different workers have used cultures obtained at different times from the French laboratories. The result is variation in the experimental work that has been carried on, for little has been done to check the constancy of the characteristics of these strains. When the matter of human use first required attention in the United States, Dr. G. W. McCoy, director of the National Institute of Health, conferred with Dr. Theobald Smith, Dr. William H. Park, Dr. Eugene L. Opie and Dr. William Charles

White. It was agreed that Dr. Park and Dr. Opie should undertake to use the vaccine (with the consent of parents) in children in the United States with as careful control conditions as possible. These studies were undertaken with the approval of Dr. McCoy. One study⁴ was carried on from the Department of Health of New York City and the other⁵ from the Henry Phipps Institute in Philadelphia. The results of these studies have been published from time to time. They are among the best attempts in the world at adequate control comparisons, but one can only conclude, after studying them, that they do not provide conclusive evidence for general use of the vaccine.

It is not the purpose here to analyze the experiments by various persons in different countries but rather to offer certain conclusions based on a careful study of the data and a familiarity with several of the experiments in different countries. The whole subject has been fairly reviewed by K. Neville Irvine⁶. It may be concluded that

1. Practically all strains of BCG used in children have been avirulent. (Nothing has been said of the Lubeck disaster, as this was proved to be a laboratory accident.)

2. It has been proved that there is a definite increase in the resistance of cattle by the use of this vaccine, although it varies within wide limits and the duration of the increased resistance also varies within wide limits.

3. The evidence of increased resistance produced by this vaccine in many other species of animals is not very convincing.

4. The oral method, if one is to judge by animal experiments, is not efficient.

5. One is not justified in taking the animal experiments, even those in cattle, as a reason for universal vaccination in man.

Sufficient arguments can however be presented for the use of this vaccine in groups for which little can be done by other methods, as for example the Negroes in the South and the Indians on the reservations, where the present machinery is not adequate in view of the peculiar circumstances surrounding their condition. It would be possible, under conditions in which a high death rate prevails, over a period of twenty years to determine something of the value of BCG and also to add to our knowledge. That there is no conclusive proof of the efficacy of the vaccine in man is in part due to the short duration of the experiments and to the small number of those involved in the carefully controlled experiments as well as to the inadequacy of the accurate data on the control groups.

Current Comment

THE INHERITANCE OF ESSENTIAL PENTOSURIA

There are at least two well known types of chronic essential pentosuria, differing from each other in the nature of the pentose excreted. A simple test allows the easy identification of *l*-xyloketose in the urine and thus the positive diagnosis of this type of pentosuria. In a recent study of forty-one such cases, Lasker and her collaborators¹ believe that they obtained evidence which strongly indicates that xyloketosuria is inherited as a recessive characteristic. Twenty pentosuric families were observed. The accepted methods of plotting the cases occurring in families were followed, and four factors indicated that the inheritance of this abnormality is probably controlled by a single recessive gene. Thus, although xyloketosuria is rare in the general population, it is frequently found in families in which known cases exist. Most of the patients with pentosuria were Jews, a fact which strongly supports the contention that the disease is hereditary. The disease was found present in the children of ten families in which neither parent showed evidence of the disease. Hence, if inherited, the abnormality would almost certainly be recessive in character. Finally, one case was observed in a child born to cousins. The likelihood of members of her generation in this family showing the trait was especially great if xyloketosuria is to be considered as a recessively inherited abnormality, both because one parent had the disease and because the parents were related to each other. The authors further state that causes other than heredity may apparently produce pentosuria. They believe it possible, however, that where such causes are operative the pentosuria may have been overlooked and was not discovered until after the event that was believed to have led to its occurrence.

SELENIUM CONTENT IN WHEAT

In previous comments on the possible dangers of selenium poisoning¹ it has been pointed out that selenium in the soil is most likely to reach toxic concentrations in semiarid regions, those which furnish the great wheat fields of the world. Robinson² has recently investigated the problem further by analyzing the selenium content of wheat grown in various parts of the world. Early in the investigations it was found that nearly all the selenium present in the grain could be concentrated in the gluten fraction of the wheat. The estimation of exceedingly small quantities of selenium was difficult and the final results used therefore were the mean of duplicate and frequently triplicate analyses. A variation in the selenium content of commercially purchased wheat of from 0.1 to 1.9 parts per million was found. All wheats contain some selenium. It is improbable, according to Robinson, that

any field grown wheat is entirely free from that element. The Canadian wheat and the South African wheat with selenium contents of between 1 and 2 parts per million, show that there are soils in other countries which contain considerable quantities of this element. The presence of small amounts of selenium in random selections of commercially obtained wheat does not eliminate the possibility that there are areas represented in the mixed sample which may produce wheat with a sufficiently large content to be toxic. Thus wheat from a small plot in a larger field in Wyoming contained 27 parts of selenium per million and a toxic wheat from a small plot in a larger field in South Dakota contained 26 parts per million. No work was done on the relation between selenium and the flour milled from the wheat. Since the gluten of the wheat carries most of the selenium, the examination for selenium of the glutes proposed for special diets becomes especially interesting, since presumably the dry-land wheats would be used for gluten extractions. Of two such samples of gluten examined, one contained 0.8 part of selenium per million and the other 16 parts per million. A gluten purchased in New York contained 12 parts per million. The gluten raised by Hurd-Karrer on artificially selected soils contained 340 parts of selenium per million. A gluten of this selenium content and the gluten separated from the toxic field grown wheat would be dangerous to use and one containing 16 parts per million could hardly be considered wholesome.

MONOCYTES IN AGRANULOCYTOSIS

Rosenthal and Abel¹ believe that they can differentiate three main types of agranulocytosis at the onset of symptoms according to the predominance of certain cells. The first type is that with relative lymphocytosis, the second, agranulocytosis with unusual monocytosis (leukopenic infectious monocytosis), and the third, hypoleukocytic angina in which all the symptoms of agranulocytosis are present, including leukopenia, but without much change in the differential blood count. They now report fourteen more cases of agranulocytosis with monocytosis and attempt to show the possible relation of this form of the disease to the administration of drugs. The majority of their cases began like infections, with malaise, chilliness, weakness and anorexia. Soreness of the tongue and gums, often with ulcerations, was not infrequently observed. Cervical lymphadenopathy was present in three instances. The etiologic factors of the disease are uncertain, though it has been suggested that abnormal disturbances of the bone marrow, unusual septic processes, or the influence of drugs is largely responsible. History of drug taking was elicited prior to the onset of symptoms in nine of the fourteen cases reported. It was interesting to note, however, that in one case a preparation containing barbituric acid derivative and aminopyrine was given on six different occasions during the acute stage of the disorder but seemed to have had no influence on the favorable progress of the disease. The most striking hematologic feature of the cases reported was not only the relative increase in the percentage of monocytes but

² Robinson, W. O. Selenium Content of Wheat from Various Parts of the World. *Indust. & Engin. Chem.* 28: 736 (June) 1936.

¹ Rosenthal, Nathan and Abel, H. A. The Significance of the Monocytes in Agranulocytosis (Leukopenic Infectious Monocytosis). *Am. J. Clin. Path.* 6: 205 (May) 1936.

in several instances an actual absolute increase. The authors believe that the prognosis is more favorable in agranulocytosis accompanied by monocytosis than in other forms of the disease. In their total group of twenty-two patients so far observed, seventeen have recovered a percentage of 77. Treatment other than local applications when indicated was unnecessary in the mild cases, although in more severe ones the patients received either pentose nucleotide or liver extract intramuscularly or intravenously.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Personal—Dr. William J. Donald Lafayette, has been named health officer of Baldwin County, effective July 1, to succeed Dr. Stephen A. Durick, Bay Minette, who has resigned to enter private practice.—Dr. Joseph J. Repa, Cresson, Pa., has been added to the Alabama State Department of Health as full time pediatrician.—Dr. Charles J. Fisher, Moulton, has been appointed health officer of Lawrence County.

Pediatric Meeting—Dr. Wallace A. Clyde Fairfield, was elected president of the Alabama Pediatric Society at its eleventh annual session in Montgomery recently. Other officers are Drs. Jacques H. Baumhauer, Mobile, vice president and Martin G. Neely, Fairfield, secretary. Speakers at the meeting included:

- Dr. Daniel Lesesne Smith, Sr., Spartanburg, S. C., Upper Respiratory Infections
- Dr. Samuel F. Ravenel, Greensboro, N. C., Experiences with Nephritis in Children
- Dr. Owen H. Wilson, Nashville, Vomiting in Young Babies with Special Reference to Pyloric Stenosis
- Major Houston H. Parsons, Fort McClellan, Mumps
- Dr. John Signorelli, New Orleans, Eczema from the Pediatrician's Standpoint

ARIZONA

Dr. Wyatt Receives the Stacey Award—Dr. Bernard L. Wyatt, formerly director of the Desert Sanatorium and Institute of Research, Tucson, has received the James E. Stacey Award for 1936 awarded by the University of Cincinnati College of Medicine. The award consists of a medal and an honorarium of \$100 and is given for significant contribution in the field of focal infection. Dr. Wyatt graduated from New York University and Bellevue Hospital Medical College in 1905, and for a time was medical officer of health of the district of Abaco, Bahama Islands.

ARKANSAS

Society News—At a meeting of the Southeast Arkansas Medical Society in Lake Village, recently, Dr. Joseph F. Shuffield, Little Rock, gave a lantern demonstration on fractures, and Dr. Guy C. Jarratt, Vicksburg, read a paper on "Pyuria in Children."—At a meeting of the Ouachita County Medical Society in Camden, May 7, a motion picture on "Treatment of Burns," furnished by Dr. Grover C. Penberthy, Detroit, was shown.—Dr. Lee Vallette Parmley, Little Rock, gave his presidential address at the spring meeting of the First Councilor District Medical Society in Tyronza, June 18, on "The Trend of Medical Legislation." Other speakers included Drs. Rufus C. Shanley, Jonesboro, on "Diagnosis of Acute Diseases of the Abdomen," Robert T. Nowlin, Memphis, "Importance of Pain as a Symptom in Disease," and Charles S. Holt, Fort Smith, "Surgery in Tuberculosis."

CONNECTICUT

Personal—Dr. Benjamin G. Horning has been named superintendent of the Hartford board of health.—Dr. James C. Fox, Jr., associate clinical professor, Yale University School of Medicine, New Haven, has been appointed clinical professor of neurology, effective July 1.

DISTRICT OF COLUMBIA

Rocky Mountain Spotted Fever—Two children have been treated for Rocky Mountain spotted fever at Children's Hospital, Washington, it was reported June 9. One child was from near Upper Marlboro, Md., and the other from Chevy Chase. Thirty-nine cases have been reported in the district since 1931, with thirteen deaths. While there is no cause for alarm, it is pointed out that, in certain sparsely built up sections in the district, ticks are prevalent and may infect one with the fever. Five of the persons reported ill in the district had not been out of the city.

Personal—Miss Clara Dutton Noyes, national director of the American Red Cross Nursing Service, died in Washington, June 3, aged 66. Miss Noyes graduated from the Johns Hopkins School of Nursing in 1896 and before the World War served as superintendent of nurses at Bellevue Hospital, New York, and Johns Hopkins Hospital, Baltimore.—Clinton T. Messner, D.D.S., chief of the dental department, U. S. Public Health Service, since 1924, died in Washington, May 28. A native of Oxford, Ind., Dr. Messner served in the army medical corps during the World War.—Dr. Alice Hamilton, Boston, technical adviser on industrial poisons, U. S. Department of Labor, was presented with the national achievement award of the Chi Omega Sorority, June 22.—The honorary degree of doctor of science was conferred on Major General Charles R. Reynolds, U. S. Army, by Dickinson College, Carlisle, Pa., at its recent commencement.

GEORGIA

Additions to Staff of Health Department—Dr. Edmund S. Burwell has been appointed associate clinician in the division of tuberculosis control, Georgia State Department of Health, Atlanta. Dr. Samuel Ross Brown, recently of the U. S. Veterans' Hospital, Muskogee, Okla., will assist in the bureau of venereal disease control. Dr. Fritz A. Brink, Jacksonville, Fla., has been appointed district health officer with headquarters in Blackshear. Dr. David M. Wolfe, Augusta, has been appointed assistant chief of the division of epidemiology.

Chattahoochee Valley Meeting—The thirty-sixth annual session of the Chattahoochee Valley Medical Association will be held at Radium Springs, July 14-15. The following will be included among the speakers:

- Dr. James P. Collier, Tuscaloosa, Ala., Acute Appendicitis
- Dr. Thomas R. Littlejohn, Sumter, S. C., Cardiovascular Syphilis and Elementary Syphilis
- Dr. Seale Harris, Birmingham, Pituitary, Thyroid, Adrenal, Hepatogenous and Pancreatic Diabetes Mellitus
- Dr. Arthur Mazyck, Jr., Dothan, Ala., Carbohydrate Intolerance
- Dr. James M. Bryant, Jacksonville, Fla., Early Diagnosis of Carcinoma of the Cervix Uteri

A symposium on public health will be held Wednesday morning by Drs. James N. Baker, Montgomery, state health officer of Alabama, Thomas F. Sellers, chief of laboratories, department of public health, Atlanta, Wilbur A. McPhaul, Jacksonville, state health officer of Florida, and Dr. Joseph Yampolsky, Atlanta. Dr. Marye Y. Dabney, Birmingham, will deliver the W. J. Love Memorial Address, Wednesday afternoon, on "The More Useful Procedures in Present Day Gynecology." The session will be concluded with addresses by Drs. Orion O. Feaster, St. Petersburg, and Benjamin H. Minchew, Waycross, presidents, respectively, of the Florida and Georgia medical associations.

ILLINOIS

Rabid Dogs—The state health department has issued a bulletin asking the cooperation of the public in the proper handling of emergencies involving the risk of rabies. The department reports that during the week June 14-20, twenty-six animal heads from seventeen counties were sent to the diagnostic laboratories of the state health department for examination, and during the same period vaccine for giving the Pasteur antirabic treatment to 131 persons in twenty-four counties was sent out by the department. Up to June 30, 373 heads had been examined by the department laboratories this year, vaccine sufficient to treat 1,353 persons had been distributed, and 4,374 cases of dog bite wounds had been reported.

Chicago

Report of Behavior Clinic—There were 1,374 cases referred for examination to the behavior clinic of the criminal court of Cook County during the first five years of its existence, according to a recent report. Of this number, 1,268 received complete psychiatric, psychological and physical examinations and intensive social service investigation, six were given only physical examinations on order of the judge, sixty-four refused examination or were discharged before a complete examination.

could be made, thirty-six were short-service cases, that is, they were transferred to the psychiatrist at the House of Correction or sent to some other clinic. There were 199 patients, or 156 per cent, who were found to be actively psychotic and were committed to hospitals for mental disease, 122, or 96 per cent, were found to be so mentally defective that commitment to an institution for the feeble-minded was warranted, an additional 7 per cent were mentally defective (borderline) but not sufficiently so for commitment. 192, or 151 per cent, were found to be suffering from some mental or nervous disorder or personality defect but not serious enough to warrant commitment by the court to a hospital for mental diseases. In most of these cases treatment was recommended, 661 patients or 52 per cent, showed no evidence of organic or functional nervous or mental disease or feeble-mindedness. Under the classification "Psychoses," dementia praecox led the list of diagnoses with a total of sixty, the paranoid state was second with forty-one, and alcoholic psychosis third with twenty. Although it was intended that examinations by the behavior clinic be made after a person was convicted of a crime but not yet sentenced, the majority of cases have been referred after indictment but before conviction.

INDIANA

Hospital News—The dedication of a new \$50,000 health preventorium at the Julia Jameson nutrition camp Bridgeport, took place June 21. The building was made possible through special gifts from individuals and organizations to the Marion County Tuberculosis Association. The camp, which is operated by the tuberculosis association, opened with seventy-five children enrolled.—The medical library of the late Dr. Rud Van Sweringen, Fort Wayne, has been given to the Methodist Hospital Fort Wayne, by Mrs. Van Sweringen in memory of her husband.—As a memorial to physicians who have served in the Indianapolis City Hospital, a lane of elm trees has been started on the hospital grounds by the women's auxiliary of the Indianapolis Medical Society. This lane is a part of the memorial park surrounding the hospital which has been dedicated to physicians who have gratuitously cared for patients unable to pay. It connects the city hospital with the James Whitcomb Riley Hospital for Children and other hospitals of the Indiana University Medical Center (THE JOURNAL, July 8, 1933, p. 146).

KANSAS

Activities of State Board of Health—County medical societies will be asked to establish liaison committees to serve with the state board of health, according to the state medical journal, to aid in the further coordination of the board's activities. The state board recently established a district laboratory to serve southeast Kansas, which will occupy space in the Parsons State Hospital. Raymond E. Leach is the bacteriologist in charge.

Veteran Physicians Honored—Dr. Arthur J. Anderson, Lawrence, was guest of honor at a dinner meeting of the Douglas County Medical Society in Lawrence, May 7, in celebration of his completion of fifty years in the practice of medicine. He was presented with a silver plaque. Judge Hugh Means spoke on "Some Medical-Legal Aspects of Practice." Dr. Charles M. Stemen, Kansas City, was guest of honor at a similar celebration, May 26, held by the Wyandotte County Medical Society, the occasion was a dinner dance.

KENTUCKY

Alumni Reunion at Louisville—The University of Louisville School of Medicine conducted a two-day clinical course for alumni June 8-9. There were symposiums by the faculty on nephritis, management of injuries, the blood and hormones of the anterior pituitary. The bacteriologic and serologic laboratories of the Louisville City Hospital, which are affiliated with the school of medicine, also held open house during the two days. The second day's sessions were a house warming for a new annex to the medical school. The alumni banquet was held at the Brown Hotel Monday evening June 8 with Dr. William Barnett Owen as toastmaster. Dr. John Walker Moore, dean of the school of medicine, was chairman of the committee in charge of clinics.

Society News—Drs. Charles B. Billington, Wickliffe and John F. Dunn, Arlington, addressed the Tri-County Medical Society (Hickman, Ballard and Carlisle counties) on hypertension and acute infection of the middle ear, respectively.—Dr. George E. Rockwell, Cincinnati, addressed the Harrison County Medical Society, Cynthia June 1 on Allergy as Seen by General Practitioners.—Dr. Frank T. Linton

Princeton, was elected president of the Southwestern Kentucky Medical Association at its annual meeting in Paducah, May 19.—Dr. Walter Dean, Louisville, was elected president of the eye, ear, nose and throat section of the Kentucky State Medical Association at the annual meeting of the section in Louisville May 22, succeeding Dr. Frank C. Thomas, Lexington.

MASSACHUSETTS

Personal—Dr. John L. Jacobs, New York, has been appointed associate professor of pathology and bacteriology at Tufts College Medical School, Boston, effective July 1, it is reported.—Dr. Vincent P. Cummings has been appointed city physician of North Adams to succeed Dr. William F. McGrath.

Society News—Dr. Kurt E. J. Lande, New York discussed "Forensic Medicine in Europe, Legal Medicine in America" before the Harvard Medical School, May 21.—Dr. Louis E. Phaneuf, Boston, discussed "Pelvic Infection in Women" before the South End Medical Club, Boston, June 16.—Recently elected officers of the New England Physical Therapy Society are Drs. Claude L. Payzant, Boston, president, George B. Carr, Lynn, and Chester S. Leach, Brattleboro, Vt., vice presidents, and William D. McFee, Boston, secretary.

MICHIGAN

Personal—The honorary degree of doctor of science was conferred on Dr. Roy D. McClure, Detroit, by Ohio State University, Columbus, June 15.—Dr. Walter J. Cree was given the honorary degree of master of science at the annual commencement exercises of Wayne University, Detroit, June 18.

Bureau of Information—The organization of a bureau of information by the public relations committee of the Michigan State Medical Society is under way, according to a recent announcement. It was pointed out that the work of the bureau will eventually necessitate the creation of speakers' bureaus in all county medical societies, bringing the physician in closer contact with the public.

Canfield Memorial Lecture—Four hundred dollars has been given to the board of regents of the University of Michigan School of Medicine by Phi Rho Sigma fraternity as the nucleus for a memorial lectureship fund in honor of the late Dr. Roy B. Canfield, professor of otolaryngology at the school. The fraternity expects to add other donations from time to time. When the principal reaches such a sum that the annual income from it, in the opinion of the medical faculty and of the president and regents, will serve as an appropriate honorarium to the person or persons chosen to give the lecture, the Dr. Roy Bishop Canfield Memorial Lecture will be inaugurated.

Changes at the Medical School—Elizabeth C. Crosby, Ph.D., has been promoted to professor of anatomy in the University of Michigan School of Medicine, Ann Arbor, and Dr. Erwin E. Nelson, to professor of pharmacology. Other changes include:

Charles R. Brassfield, M.S., to assistant professor of physiology.
Dr. Frank Hartsuff Bethell, assistant professor of internal medicine.
Dr. Stanley M. Goldhamer, assistant professor of internal medicine.
Dr. Franklin Davis Johnston, assistant professor of internal medicine.
Dr. Don Marshall, assistant professor of surgery.
Dr. Luis Iglesias, assistant professor of surgery.

The Edward Swift Dunster Scholarship has been made available at the medical school. The interest from a fund of \$1500 will be used for the scholarship, which is named in honor of the late Dr. Dunster, who was for many years a professor in the medical school. Dr. Dunster died in 1888. Dr. Max M. Peet, professor of surgery at Michigan, was honored in May when a bird, *Botaurus lentiginosus peeti*, a variety of American bittern was named for him. Dr. Peet has been a student of ornithology for thirty years and possesses a fine collection, the *University Hospital Bulletin* reports.

MINNESOTA

Personal—Dr. Charles H. Mayo, Rochester, has been named professor emeritus of surgery of the medical and graduate schools, University of Minnesota.—Dr. James R. Kingston, Deer River, has been appointed health officer of the northern district of Minnesota with headquarters in Bemidji. The district is composed of Koochiching, Itasca, Hubbard and Beltrami counties.

Georgopoulos Sentenced for Illegal Practice—George D. Georgopoulos pleaded guilty to practicing healing without a basic science certificate in municipal court, Faribault, May 16 and was sentenced to pay a fine of \$500 and costs or serve six months in the Rice County jail. He was unable to pay the fine and was placed in jail. The defendant had examined and treated a tuberculous patient at Faribault and received \$20. In

his room in St Paul, a trunk was found full of medicine and medical instruments. When arrested he stated he had a license but produced instead two diplomas bearing the name Reliable Laboratories, St Paul, Minn. One of the diplomas was in hematology and urinalysis and the other in physical therapy. Georgopoulos stated that the school was operated by one Philip Stern in the Pittsburgh Building, St Paul. He claimed he attended a course for two months to secure the diploma in hematology and urinalysis for which he paid \$140. He went another month to get the diploma in physical therapy, for which he paid \$15. He admitted having treated several patients his fees ranging from \$2 to \$10 for each patient. He was arrested in St Paul in 1929 for a similar offense at which time he pleaded guilty and paid a fine of \$250. Subsequently in federal court he was denied citizenship because of his unlawful practice of medicine.

MISSISSIPPI

Personal—Dr Cecil C Smith, Indiana formerly director of the Sunflower County Health Department has been placed in charge of the Pearl River County Health Department. Poplarville. He has recently returned from a year's study at Johns Hopkins School of Hygiene and Public Health Baltimore, where he received the certificate in public health.

Society News—Dr Willard H Parsons Vicksburg, addressed the First Mississippi Medical Society in Philadelphia June 18, on "Reduction of Surgical Mortality."—The George County Medical Unit was reorganized at a meeting April 7 and application for a charter filed. Speakers at a meeting, June 5 were Drs James A Dorsett and Jack L Spiceland Lucedale, on 'Proper Use of Anesthesia in Labor and Tannic Acid Treatment of Burns' respectively.—Dr Robert E Wilson, Greenville, addressed the Issaquena-Sharkey-Warren Counties Medical Society in Vicksburg June 10 on 'Erysipelas in Children'.

NEVADA

Plague-Infected Ground Squirrels—Plague infection has been identified in ground squirrels shot on a sheep ranch near Lamoille in Elko County recently the U S Public Health Service reports. The infection was determined by inoculating guinea pigs with fleas removed from fifty ground squirrels. It was said that previous examinations of hundreds of squirrels had not revealed any suggestive lesions.

NEW HAMPSHIRE

Veteran Physicians Honored—At the recent annual meeting of the New Hampshire Medical Society Dr Ellen A Wallace, Manchester, received a gold medal in recognition of her membership in the society for fifty years. At the same time honor was paid to Drs Frederick L Hawkins Meredith and John F Robinson, Manchester, who have been in practice fifty years.

Society News—Dr Benjamin P Burpee Manchester discussed obstetrics before the Strafford County Medical Society, Rochester, in April.—Drs Clifford L Derick Boston, and Elmer J Brown Manchester, addressed the Hillsborough County Medical Society Nashua, April 28 on 'Staphylococcus Infections and Their Treatment' and 'Medical and Surgical Treatment of Prostatism' respectively.

NEW JERSEY

Personal—Dr Ellen C Potter, director of medicine of the New Jersey Department of Institutions and Agencies, received the honorary degree of doctor of laws at the annual commencement of the New Jersey College for Women, New Brunswick, June 6.

State Medical Election—Dr Spencer T Snedecor, Hacksack was chosen president elect of the Medical Society of New Jersey at the annual meeting in Atlantic City June 3. Dr Francis R. Haussling, Newark, was installed as president, Drs William G Herrman, Asbury Park, and William J Carrington, Atlantic City, were elected vice presidents and Dr John B Morrison, Newark, reelected secretary.

NEW YORK

Personal—Dr Joseph Frederick Painton, Buffalo, has been appointed associate in medicine at the University of Buffalo School of Medicine.—Dr Max J Schwerdt, Staten Island, was guest of honor at the annual dinner of the Richmond County Medical Society in April, celebrating his fiftieth anniversary in the practice of medicine.—Dr Hickson Field Hart, Peekskill, celebrated the fiftieth anniversary of his graduation from the College of Physicians and Surgeons New York, May 13.

Hospital News—The name of Bloomingdale Hospital, White Plains, which is affiliated with New York Hospital, New York, has been changed to New York Hospital, Westchester Division. The Westchester institution has been conducted by the Society of the New York Hospital since 1821. Dr Clarence O Cheney, formerly director of the New York State Psychiatric Institute, New York, was recently appointed medical director (THE JOURNAL, March 14, p 929).—Dr Hobart A Burch, Rochester, Minn., has been appointed director of the x-ray department of St Joseph's Hospital, Elmira.

Board of Psychiatric Examiners—Under the provisions of a law passed by the 1936 legislature establishing a board of qualified examiners in the state department of mental hygiene, the following have been appointed to constitute the board: Drs Frederick W Parsons, commissioner of mental hygiene, Vernon C Branham, Woodbourne, appointed by the commissioner of correction, Lloyd H Ziegler, Delmar, appointed by the superintendent of education, and Israel Strauss, New York, selected by the Medical Society of the State of New York. The code of criminal procedure has been amended to require that courts appointing a commission to examine persons charged with crime include at least one qualified psychiatrist.

New York City

Deaths from Alcoholism Decrease—A compilation of deaths from alcoholism reported to the New York City Department of Health since 1931 shows that these deaths have decreased in the past five years. In 1931 there were 794 deaths, 1932, 574, 1933, 666, 1934, 596, and 1935, 509. There has also been a sharp decrease in the number of deaths and serious illness from alcohol poisoning, the report said.

Personal—Dr Herbert C Chase has been appointed professor of surgery at New York Polyclinic Medical School and Hospital.—Dr Stephen P Jewett, clinical professor of psychiatry, New York Medical College and Flower Hospital, has been appointed director of the neurologic division of Metropolitan Hospital.—The Society of Alumni of Bellevue Hospital celebrated its fiftieth anniversary recently and presented a watch and chain to Dr Leroy W Hubbard, Mount Vernon, N Y, sole survivor of the nineteen founders.—Dr Howard Fox was recently elected an honorary member of the Austrian Dermatologic Society.

Changes at New York University—Dr Harold D Senior, professor of anatomy and director of the anatomic laboratories at New York University College of Medicine since 1910, has been made professor emeritus. The college announces the appointment of Dr Frederic Wertham as assistant clinical professor of psychiatry, effective in September. Dr Irving Graef has been promoted to be associate professor of pathology, Drs Lauretta Bender and Nathaniel Ross, assistant clinical professors of psychiatry, and Walter Bromberg, assistant clinical professor of psychiatry, all effective in September. In recent months Drs Albert A Epstein, Isidore W Held and Thomas A Martin have been appointed clinical professors of medicine and Dr Karl M Bowman professor of clinical psychiatry. In addition the following promotions have been made:

Dr Harrison S Martland professor of forensic medicine
Dr Howard C Taylor Jr associate professor of obstetrics and gynecology

Dr Wilhelm Bierman assistant clinical professor of therapeutics.
Drs Anthony S Bogatko, Victor Carabba, Thomas J Galvin, Francis M Harrison, John H Mulholland, Joseph Nash, John Nelson, Harry A D O'Connor, Samuel Standard and Hippolyte M Wertheim assistant clinical professors of surgery.

Ninth Graduate Fortnight—The subject of the ninth annual Graduate Fortnight of the New York Academy of Medicine, to be presented October 19-31, will be "Trauma, Occupational Diseases and Hazards." Twenty-two hospitals will offer coordinated afternoon clinics and clinical demonstrations, and evening sessions will be held at the academy. Among speakers who will address the evening sessions are:

Dr Henry E Sigerist, Baltimore Historical Background
Dr John J Moorhead Accidents and Their Management
Dr Marvin A Stevens Hazards in Athletics
Dr Foster Kennedy Fatigue and Noise in Industry
Drs Henry H M Lyle, New York Harry L Gilchrist Washington D C and Col. Adeline Gibson U S Army Governors Island N Y, War Injuries and Emergencies
Dr William Darrach General Principles of Fracture Treatment
Alexander O Gettler Ph D Toxicology of Industrial Poisonings
Dr Alice Hamilton Boston Medical Legal Aspects of Industrial Poisonings
Dr Temple S Fay Philadelphia Injuries to the Head
Dr Byron P Stookey Injuries to the Spine

A scientific exhibit of books, pathologic and research material, apparatus for resuscitation and other first aid appliances will be assembled and demonstrations will be held at regular intervals.

NORTH DAKOTA

Hospital News—A new seven story building is being erected at the North Dakota State Hospital, Jamestown, according to the *American Journal of Psychiatry*. The building, which will furnish infirmary care and treatment for 450 patients, will cost \$360,000, part of which is supplied by the federal government and the remainder by the state.

OHIO

Personal—Dr. Will M. Hoyt, Hillsboro, has been appointed health officer of Highland County.—Dr. Burrell Russell, New Philadelphia, has been appointed a member of the board of trustees of Ohio State University, Columbus.—Dr. Henry P. Worstell, Columbus, has been appointed orthopedic consultant to the medical division of the state industrial commission.—Dr. Archie J. Martin, who recently completed his internship at the Ohio Valley General Hospital, Wheeling, W. Va., has been appointed health commissioner of Belmont County.—Dr. Chester W. Waggoner, Toledo, has been appointed to the state medical board for a term of seven years. He succeeds Dr. James G. Blower, Akron.

Society News—Dr. Murat H. Cherrington, Logan, spoke on epidemic encephalitis at a meeting of the Hocking County Medical Society, Logan, May 14.—Dr. Edward H. Wilson, Columbus, addressed the Hempstead Academy of Medicine, Portsmouth, May 11, on "Nonunion of Fractures".—Dr. Harley O. Bratton, Columbus, addressed the Morrow County Medical Society, Mount Gilead, May 12, on "Medical and Surgical Treatment of Prostatic Hypertrophy".—Dr. John E. Greiwe, Cincinnati, addressed the Warren County Medical Society, Lebanon, on "The Electrocardiogram and the Coronary Circulation".—Dr. George I. Nelson, Columbus, discussed treatment of heart failure as the guest of the Auglaize County Medical Society, Wapakoneta, June 11.—Dr. Louis Mark, Columbus, addressed a joint meeting of the Miami and Shelby county medical societies at Sidney, June 4, on "The Modern Trend in Treatment in Tuberculosis".—The Stark County Medical Society recently began publication of a quarterly bulletin.—Dr. Charles C. Wolferth, Philadelphia, addressed the Mahoning County Medical Society, Youngstown, June 16, on cardiovascular disease.

OREGON

Society News—Drs. Edward C. Bull and LeRoy H. Briggs, San Francisco, were guest speakers before the Southern Oregon Medical Society at its annual meeting at Klamath Falls in May, on "Fracture of the Tibia and Fibula Involving the Ankle Joint" and "Nonpulmonary Tuberculosis" respectively. Dr. Elza D. Johnson, Klamath Falls, president of the society, gave his official address on "The Ancient Art of Prescription Writing".

PENNSYLVANIA

Hospital News—The state department of welfare is making a census of county mental hospitals to supplement data on state-owned institutions.

Cancer Meeting—The Cambria County Medical Society held an all day cancer meeting for physicians and the public in Johnstown June 11. Speakers were Drs. George E. Pfahler, Philadelphia, Edwin A. Merritt, Washington, D. C., William F. MacFec, New York, Samuel J. Waterworth, Clearfield, Walter M. Bortz, Greensburg, and George W. Grier, Pittsburgh. Drs. Laurrie D. Sargent, Washington district counselor and Alexander H. Colwell, Pittsburgh, president of the Medical Society of the State of Pennsylvania, also appeared on the program.

Philadelphia

Hospital News—The Preston Retreat celebrated the centenary of its chartering, June 14. The building was completed in 1840, but lack of income prevented it from opening until 1865. Dr. John Cooke Hirst is medical director of the fifty-bed maternity hospital.—The first annual banquet of the ex-resident physicians of St. Joseph's Hospital was held at the Bellevue-Stratford recently with Dr. James A. Kelly as toastmaster.

Faculty Changes at Temple—New appointments to the faculty of Temple University School of Medicine include the following:

Dr. John F. Huber, associate professor of anatomy
Dr. Thomas M. Durant, associate professor of medicine
Dr. George Elbert Farrar, Jr., assistant professor of medicine
Dr. David Soloway, assistant professor of histology and embryology
Dr. Walter S. Cornell and T. Ruth Weaver and Lyle Jeanne Ch.E., assistant professors of hygiene, sanitation and public health.

The promotion of Dr. Harriet L. Hartley to be professor of hygiene, sanitation and public health was also announced.

Pittsburgh

The New Allegheny General Hospital—The Allegheny General Hospital, first opened fifty years ago with fifty beds, dedicated a new building with a capacity of 600 beds June 22-26. Dr. Morris Fishbein, Chicago, editor of *THE JOURNAL*, and Mr. E. H. Foley Jr., director of the legal division of the Public Works Administration, were the speakers at the formal dedication June 24. Work on the new building was begun in 1929 after a fund of \$5,000,000 had been raised by popular subscription. In 1931 construction was halted because of the depression and was resumed in 1935 with a loan of \$2,000,000 by the Public Works Administration. The hospital is of the skyscraper type with a central stem twenty floors high and wings set back at intervals. It has nine floors for private patients, one for semiprivate patients and two for ward patients. One is devoted to care of children. The obstetric department

The New Allegheny General Hospital

occupies the fifteenth, sixteenth and seventeenth floors. One wing houses the Singer Memorial Laboratory, running from the basement and including the third floor. The outpatient department and various special departments are on the second floor. Dr. Gustav Walter Zulauf is superintendent of the hospital.

TEXAS

Health at San Antonio—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended June 27, indicate that the highest mortality rate (21.6) appears for San Antonio and for the group of cities as a whole, 10.9. The mortality rate for San Antonio for the corresponding period last year was 15.6 and for the group of cities, 10.5. The annual rate for eighty-six cities for the twenty-six weeks of 1936 was 12.9 as against a rate of 12.2 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Special Society Elections—Dr. Edward H. Schwab, Galveston, was elected president of the Texas State Heart Association at the recent annual meeting and Dr. Robert M. Barton, Dallas, secretary. Drs. Arthur J. Schwenkenberg, Dallas, was made president of the Texas Neurological Society and Dr. Wilmer L. Allison, Fort Worth, reelected secretary. The Texas Railway Surgeons Association elected Dr. Charles E. Scull, San Antonio, president, and Dr. Ross B. Trigg, Fort Worth, secretary. Dr. George B. Cornick, San Antonio, was made president of the Texas Pediatric Society and Dr. Frank H. Lancaster, Houston, was reelected secretary. At the meeting of the Texas Dermatological Society, Dr. Culver M. Griswold, Houston, was elected president and Dr. Everett R. Seale, Houston, reelected secretary. All these societies met in Houston during the annual session of the State Medical Association of Texas.

WASHINGTON

Society News—Dr. Morris Fishbein, editor of *THE JOURNAL*, addressed the King County Medical Society, Seattle, July 2, on "New Forms of Medical Practice".—Dr. Howard B. Kellogg, Seattle, addressed the Cowlitz County Medical Society, Yakima, in May on "Diagnosis and Treatment of Thromboangiitis Obliterans" and Mr. Harry Mackler, chemist, on "Irritating Properties of Smoking Tobaccos".—Drs. Walter

Kelton, Seattle, and Herbert W E Johnson Everett, addressed the Snohomish County Medical Society, Everett May 7, on "Chavide Crutch Splint" and Injection Treatment of Hemorr respectively

WEST VIRGINIA

State Medical Meeting and Election—Dr William S Fulton, Wheeling, was chosen president of the West Virginia Medical Association at the annual session in Fairmont, June 8-10, to take office January 1, succeeding Dr Charles G Morgan, Moundsville. Drs George R Miller, Fairview and Frank C Hodges, Huntington, were elected vice presidents. Guests of honor at the meeting were

Dr Lawrence T Royster Charlottesville Va Rheumatic Heart Disease in Children
Dr Frank H Lahey Boston Collstones and Ulcers
Dr Arthur M Fishberg New York Coronary Thrombosis
Dr James Homer McCready Pittsburgh Status of the Allergic Nose in Sinusitis Hay Fever and Asthma
Dr George R Livermore Memphis Tenn Diseases of the Prostate
Dr Warren T Vaughn Richmond Va Newer Methods in the Diagnosis and Treatment of Food Allergy
Dr George Alvin Ulrich Philadelphia Breech Presentations

Dr Frank C Hodges Huntington delivered the annual oration on medicine, on "The Diagnostic Value of Intradermal Injections," and Dr Russell B Bailey, Wheeling the oration on surgery, on "Thoracic Surgery." Dr Thurman B Rice Indianapolis, was the speaker at the annual banquet, Wednesday evening, June 10, at the Fairmont Hotel, on health fads. The West Virginia Heart Association, the West Virginia Society of Industrial Physicians and Surgeons and the West Virginia Society of Obstetricians and Gynecologists held their annual sessions during the week. Tuesday afternoon June 9 a monument to the founders of the association was dedicated at Rivesville

GENERAL

Fever Therapy Conference Postponed—The First International Conference on Fever Therapy which was to have been held in September, has been postponed to March 30 April 2, 1937. Sessions will be held at the College of Physicians and Surgeons of Columbia University New York. A tour has been arranged to follow the conference to enable physicians to observe methods of fever therapy used in various hospitals. The American committee consists of Dr Walter M Simpson, Dayton, Ohio, chairman, William Bierman, New York, Frank W Hartman, Detroit, Leland E Hinsie, New York, Clarence A Neymann, Chicago, and Stafford L Warren, Rochester, N Y. Further information may be obtained from Dr Bierman, 471 Park Avenue, New York.

Child Neurology Research—With a grant from the Friedsam Foundation, a special committee is to be formed under the direction of Dr Bernard Sachs New York, to stimulate research in child neurology and allied fields, so that physicians and other scientists may contribute to the thorough investigation of problems bearing on the care and cure of those afflicted with any of the nervous and mental disorders from birth through adolescence. This work is to be nationwide in scope and is to be encouraged by stipends, scholarships or otherwise and is not to be limited to special groups or institutions. The committee is to be made up of two neurologists in addition to Dr Sachs, the director, two pediatricians, one orthopedic surgeon and two laymen. The foundation has been established to carry out the bequests and intentions of the late Colonel Michael Friedsam, who was greatly interested in child health and welfare. The trustees have agreed that neurology and psychiatry have important relations to the early training of children, to development of character and to general medical and home conditions, and that the problems of child health and welfare may be properly considered to be closely allied fields for investigation. Details of the program already under consideration will be announced early in the autumn. After September 10, communications may be addressed to Child Neurology Research, Bernard Sachs, M D, Director, 116 West Fifty-Ninth Street, New York.

Provisional Figures for Fourth of July Accidents—Traffic accidents led the list of causes of death in Fourth of July accidents, accounting for 254 lives throughout the nation, the Chicago Tribune reported. Seven fatalities from firecrackers were reported, according to a compilation of the Associated Press. The American Museum of Safety reported the injury of at least 7,738 persons and thirty deaths in a compilation of Fourth of July accidents in 1935. More deaths were recorded for the holiday this year than for the previous five years, with a provisional total of 444 deaths. One hundred and four persons were drowned, while miscellaneous tragedies accounted for

thirty-seven more in fifteen states. In New York City 591 persons were treated at hospitals for fireworks burns. Two men were killed at Lexington, Mich., when fireworks blew up on a scow during the celebration there, and sixteen spectators at a community fireworks display at Findlay, Ohio, were hurt by a noise bomb that shot across the river into the crowd instead of rising in the air as expected. 343 injuries were attributed to fireworks in St Louis. Kansas City, which has an anti-firecracker ordinance, reported 100 injuries with no deaths, 300 minor fireworks injuries were reported in northern California. In Remsen, Iowa, fifteen families were homeless on account of a fire started when a little girl's firecracker was lighted in a tent near a cafe. Business establishments covering four blocks were in ruins, with the estimated damage reported at \$1,000,000.

Society News—The Eastern section of the American Congress of Physical Therapy held a meeting in Philadelphia, May 27-28. Speakers the first day included Drs Norman E Titus New York, on "Treatment of Erysipelas with Ultraviolet Energy," Gervase J P Barger, Washington, D C., "Fever Therapy in Office Practice" and John de P Currence, New York, "Physical Therapy in Treatment of Arthritis." The second day was devoted to clinics at Jefferson Hospital and a joint meeting was held with the Philadelphia County Medical Society the evening of May 27.—Dr John H Stokes, Philadelphia, was elected president of the American Dermatological Association at its annual meeting, June 5, Dr Frederick D Wedman, Philadelphia, is secretary.—The American Otolological Society elected Dr Edmund P Fowler, New York president for the coming year, Dr Thomas J Harris New York, is secretary.—At a meeting of the Association for the Study of Internal Secretions, May 12, Dr Francis M Pottenger Monrovia, was chosen president, and Dr Eberle Kost Shelton Santa Barbara, secretary. The next annual session will be held at Atlantic City.—A W Jones, St. Louis executive secretary of the St. Louis Tuberculosis and Health Association was elected president of the National Conference of Tuberculosis Secretaries at its annual meeting in New Orleans in April.—Dr Munford Smith, Los Angeles, was chosen president of the American Sanatorium Association at the annual session in New Orleans in April.

Pan American Conference of Health Directors—The third Pan American Conference of National Directors of Health was held in Washington in April with representatives from South and Central American countries, Mexico and Cuba present. Dr Hugh S Cumming, former surgeon general of the U S Public Health Service, was elected president of the conference and Dr João Barros Barreto, Brazil, general secretary. Among the subjects discussed was a report on modern trends in public health. The conference recommended establishment of scientific services especially charged with the study of problems of public health, distinct from those concerned with health administration, it recommended also study in each country of methods of sewage disposal, investigations of industrial diseases and accidents, especially pneumoconiosis, extension of maternity centers and education of women in health matters. A report on health problems in high altitudes, presented by the delegate from Peru, prompted the conference to suggest that countries with inhabited high plateaus organize institutes to study these problems and report to the Tenth Pan American Sanitary Conference in 1938. Consideration was given to the subject of nutrition. The conference urged active campaigns against drug addiction, improvement in control over traffic in narcotics and investigation of results obtained by enforcement of international agreements. Other topics discussed at the conference were amebiasis, leprosy, poliomyelitis, trachoma, venereal disease, malaria, the carrier problem and vaccines.

CORRECTIONS

Dural Sac Instead of the Cord—In Dr Walter D Abbott's paper on "Compression of the Cauda Equina by the Ligamentum Flavum," published in THE JOURNAL June 20, the words dural sac should have been used instead of the words "the cord," in lines 5 and 6, page 2130.

Reference to Ergotamine Tartrate—A reference to Dr S S Lichtman's communication to the editor, entitled "Clinical Use of Ergotamine Tartrate," inadvertently was left in the index in the June 27 issue of THE JOURNAL. This communication was withdrawn from the pages at the last moment to provide space in that issue for the obituary of Dr Tate Mason, President of the Association, whose death occurred a few hours before THE JOURNAL went to press. Dr Lichtman's communication appears in the present issue, page 148.

Decline in Medicinal Use of Alcohol

At one time alcohol was extensively prescribed in England for the treatment of disease, mainly for its supposed action as a stimulant, but its use has been diminishing, as shown by figures given in a booklet by Dr C C Weeks entitled "Alcohol in Hospital Practice." Combining the figures of every class of hospital, he found that in 1900 with 383,000 patients the average cost of alcohol per patient was 20 cents, which in terms of brandy is equivalent to $6\frac{3}{10}$ ounces. In 1923 with 670,800 patients the average cost was 16 cents per patient, equivalent to $1\frac{3}{10}$ ounces of brandy. The much greater reduction in the brandy than in the cost is due to a great increase in the cost of alcoholic drinks since the war. In 1934 with 1,704,222 patients, the cost was 75 cents equivalent to $\frac{9}{100}$ ounce per patient. In the great London hospitals the decrease in thirty-four years has been from 10 ounces per patient to less than 1 ounce, and in the provincial hospitals from nearly 8 ounces to about three-fourths ounce. Since 1889 the spirits used in mental hospitals of the London County Council have been reduced from 20 ounces to less than one-fifth ounce per patient.

Dr Weeks attributes the reduction to the convergent effect of many lines of evidence regarding the nature and action of alcohol, from physiologic and pharmacologic investigation and a clearer recognition of its pathologic action. Clinically it has been shown that when alcohol is withheld the death rate from pneumonia, for example, is reduced and the period of convalescence from infectious diseases shortened. Prof John Hay contrasted the cases of pneumonia treated at the Royal Southern Hospital, Liverpool, with and without alcohol. He wrote:

The results were remarkable. They left no doubt in my mind that alcohol given to fortify and strengthen the heart failed in its purpose, and instead of helping the patient to fight the infection materially diminished his chances of recovery. The average age in each group was 35 years. Deleting the cases moribund on admission, the mortality in the cases treated with alcohol was 36.8 per cent in those treated without alcohol 21.4 per cent. At the Western Fever Hospital, London Dr J D Rolleston found that in the year before he became superintendent 2,589 ounces of brandy had been used while in the early months of 1926 914 ounces had been used. As a result of his advice and example only 77 ounces was used in the rest of the year. In 1927 25 ounces was used in 1928, 1 ounce. Since then neither in the hospital nor in the extensive ambulance service has any wine or spirit been used in the treatment of many thousands of patients. In the army the strong tradition in favor of the issue of a rum ration after exposure to cold and wet is dying out. A new regulation, issued in 1926 provides for the issue of a ration of rum or a pint of cocoa.

Broadcasting an appeal on behalf of the National Temperance Hospital, Lord Moynihan said: "It has done national work in demonstrating that the routine use of alcohol in the treatment of disease is unnecessary. It is difficult to realize that fifty years ago the use of alcohol was considered necessary in the treatment of disease and for the maintenance of good health. In 1873 the hospital began its work. The general attitude of the medical profession was antagonistic. In one of the leading medical journals of that time the doctors of the hospital were solemnly warned that there was such a place as Newgate (the well known gaol) and that their rash attempt to treat disease without alcohol might result in conviction for manslaughter."

Today medical science is of one mind that alcohol, while it has its uses, is unnecessary and often harmful in the routine treatment of disease."

The Medical Research Council's Alcohol Investigation Committee reported: "The popular belief in alcohol as a remedial action on the heart or the respiration and on the vital activities in general. Rational medicine has long abandoned this belief, but it still lingers in popular practice."

Beer Preferred to Milk

The desirability of increased consumption of milk by the nation has of late been frequently emphasized in the press. It is among the lower classes especially that the consumption of milk is deficient. But statistics supplied by G B Wilson, consulting secretary to the great temperance organization, the United Kingdom Alliance, shows that they prefer to spend the money derived from returning prosperity on alcoholic beverages. The year 1935 has been one of more employment and more spending of money. The nation consumed 22,710,000 bulk barrels of beer, an increase of 4.9 per cent over 1934 and of 17 per cent over 1933. On this beer the nation spent \$750,000,000. The estimated consumption of liquid milk was 802,000,000 gallons as against 817,000,000 gallons of beer. The price paid for the milk was \$415,000,000, as against \$750,000,000 for the beer. The deficient consumption of milk by the lower classes is shown by the dietitian Sir John Orr in his work entitled "Food, Health and Income." Thirteen and one-half million persons with weekly incomes of \$7.50 and over per head drank 400 million gallons of milk a year, while the same number of persons with incomes under \$4 drank only 240 million gallons.

Drug Smuggling in Ships

At the meeting of the Advisory Committee of the League of Nations in Geneva the United States delegate, Mr Stuart Fuller, proposed drastic measures for the prevention of the illicit traffic in opium and other dangerous drugs. He asked that the owners of ships in which contraband drugs were found might be liable to fines and that notices of reward for information which might lead to seizures should be posted prominently in passenger and cargo vessels and in harbors. Penalties for smuggling should be posted in conspicuous places in these ships. He cited as a good example the warning issued by the British government. The custom of permitting visitors on board vessels on sailing day presented a special problem. They should not be allowed to go on board without special permission and should not be allowed to leave the ship without passing through the customs. In a large liner the ship's company should include detectives who could mingle with the passengers. The Canadian delegate, Colonel Sharman, said that in his country it had been necessary to maintain patrol boats at night to prevent contact between the crew and passengers from the shore. On the other hand Mr G S Hardy, delegate for India, said that experience in that country showed that it might not be always wise to hold owners or officers of a ship responsible for contraband found on board. It was suggested that the help of the seamen's unions should be sought in combating drug traffic in ships.

Silicosis in Coal Miners

The results of an investigation into the causes of miners' silicosis, particularly in the South Wales anthracite coal field were set forth in a paper read to the Institute of South Wales Engineers by Dr T D Jones, professor of mining at the University College of South Wales. He said that research at the Banting Institute, Toronto, showed that inhalation of small quantities of nitrous fumes with silica dust immensely increased the rate of formation of fibrous nodules in the lungs. This fact caused the matter to be taken up by the explosive experts.

and important conclusions had already been reached. The experiments carried out proved that the principal factor affecting the proportion of nitrous fumes was the wetness or dryness of the condition of firing. The connection between nitrous fumes and silicosis raised the whole question of ventilation in relation to shot firing. It was not the amount of firing done but the conditions in which it took place that mattered. From a comprehensive statistical survey his deduction was that the harm attributed solely to dust in anthracite mines was the result of a number of factors, an important one being exposure to cold on the trolley trains taking men in and out of the collieries. Protection of the men on these would go a long way to prevent silicosis. As to the curative treatment experts on pulmonary disease should take up the matter at once and the Welsh National Memorial Association should make provision for the treatment of silicotic cases, even though tuberculosis was absent.

Sterilization of the Unfit

By a large majority the National Conference of Labor Women adopted a resolution for legalizing the voluntary sterilization of the unfit. Dr. Caroline Maule recommended this for persons who were mentally defective or suffering from mental disorder or believed to be carriers of grave physical disability which had been shown to be transmissible; also persons believed to be likely to transmit mental disorder or defect. This voluntary sterilization should be subject to safeguards. Referring to the Roman Catholic opposition to voluntary sterilization she said that no one who felt strongly on the question had a right to impose their views on Protestants or agnostics. As the suggested bill made sterilization voluntary Roman Catholics would not have to be sterilized if they did not wish to be. Another physician, Dr. Edith Summerskill said that she supported voluntary sterilization on purely medical grounds as a form of preventive medicine. The time was coming when they should prevent people from getting sick. The resolution was opposed by Miss Spencer of the University Labor Federation who suggested that it might be dangerous to put a piece of legislation through which could be used for other ends. The vote by a show of hands, gave a large majority in favor of the resolution.

Registration of the Mothers' Age at Birth

Though English vital statistics have been carefully compiled and made the subject of scientific investigation for many years, it is curious that while every birth has to be registered the important fact of the mother's age is not included in the particulars required, as it is in most civilized countries. It is an essential datum in investigating the recent decline in fertility. Its absence has compelled statisticians when dealing with this subject to have recourse to the tables of other countries where the mother's age is registered and apply them to the English birth rate, so as to draw a conclusion as to the English birth rate at the various ages. This may be a reliable method but it is obviously not so satisfactory as the actual figures. In reply to a question in parliament the minister of health stated that it had been for some time the intention to make the necessary alteration in birth registration on the first suitable occasion.

Pollenarium for St. Mary's Hospital

The inoculation department of St. Mary's Hospital has extended its laboratories by the construction of a pollenarium (a building for the collection of grass pollen) which is used in the diagnosis and treatment of hay fever. During 1935 Lord Iveagh, chairman of the inoculation department grew for it six separate crops of grasses and grain for the collection of pollen with which to treat hay fever. The pollenarium has been built alongside the crops, so that the pollen can be collected under the best conditions. Some 28 pounds has been collected, which represents 580,000 million million grains.

Annual Report of Social Insurance for 1934

The secretary of labor, whose department administers the social insurance law, has published his report of the application of the law for 1934. The total received as premiums during 1934 was a little over 3 billion francs (about 192 million dollars). This was about 130 million francs (about 10 million dollars) less than the average sum received during the period since 1930. Seven million individuals paid premiums during 1934 the average amount paid by each insured person was about 240 francs (14 dollars) as compared to 280 francs in 1930-1931. The total received in francs as premiums was distributed as follows: 1,378 million francs to the 'caisses de repartition' which provide for old age and invalidity (permanent) insurance, 1,238 million francs to the 'caisses de capitalisation', which act as a sinking fund for the social insurance law, 78 million francs to the unions de reassurance et caisses de garantie, which serve as a sort of savings bank for the 'caisses' or distributing agencies dealing directly with sickness claims.

Expenditures for sickness, invalidity, maternity benefits and old age insurance rose from 1,086 million francs (about 66 million dollars) to 1,215 million francs in 1934. The average premium received in 1934 was 240 francs, 200 francs (on the average) being paid out as benefits. Of the latter sum, about 82 per cent represents sick benefits, 14 per cent maternity insurance, 3 per cent death claims, and miscellaneous disbursements 1 per cent.

Invalidity has functioned only since 1933 hence comparatively little has been disbursed under this heading so far. Seventy per cent of the permanent invalidity claims were made by insured suffering from pulmonary tuberculosis, 8 per cent from tabes or general paralysis of the insane, and 4 per cent from cancer. The total administrative personnel is 7,000, or less than one official for each thousand insured persons.

The social insurance law has been in force since the fall of 1930 yet this report of the minister of labor has been unable to throw any light on (a) which diseases give rise to the greatest amount of reimbursement by the caisses (b) the age periods in which morbidity and mortality rates are highest, (c) how much is disbursed for tuberculosis, measles, rheumatism and measles and (d) how much is spent on the family of the sick insured individual.

Another criticism raised by the author of an article in the *Siecle medical* of April 15, 1936, is that the agencies (caisses) which act as the primary receiving and disbursing centers have but little information in these annual reports to serve as a guide as to which individuals should be considered as good and which as poor risks.

Atropine in Postencephalitis Complications

Roemer of Wurtemberg as the result of the research work of Bremer and some personal clinical experience, found that in the majority of cases following encephalitis the complications were favorably influenced by large doses of atropine. If one began with small doses as much as 20 mg (one-third grain) could be given three times daily.

At the March 24 meeting of the Academie de medecine of Paris Marinesco and Facon of Rumania reported their results with this method of treatment in 200 cases. A solution containing 0.5 Gm (7½ grains) to one hundred cubic centimeters of water was employed. One drop corresponds to 0.25 mg (1½ grain) of atropine. The first dose given is one drop three times a day and in most cases this can be increased to three drops three times a day within ten days, then two drops for the following ten days and one drop during the rest of the

course of treatment Dryness of the throat is not a contra-indication and disappears soon If other symptoms, such as vertigo, palpitation or gastric distress appear, the dose should not be increased for several days As a rule, a larger dose is soon tolerated Roemer has given as high as from 150 to 300 drops a day, but the authors obtained excellent results in giving only 40 to 60 drops a day In all cases this amount could be reduced in a short time without interfering with the efficacy of the drug Atropine has a better effect in recent cases, especially in younger individuals, if no previous treatment, e. g., scopolamine, has been employed

The action of the atropine on the rigidity seems to be more marked than its influence on the tremor At times the latter seems to increase although the rigidity is disappearing, but, as soon as an adequately high dose is reached the tremor becomes less marked and often completely disappears The tremor in paralysis agitans is less influenced than that observed in Parkinson's disease, because of the difference in the pathologic changes in the two diseases In spite of this, atropine ought to be employed in paralysis agitans because one often observes remarkable improvement The ocular symptoms are less uniformly influenced by atropine, but nevertheless an improvement is often noted

Some cases illustrative of efficacy of the use of atropine in the postencephalitic Parkinson syndrome were cited by Marinresco and Facon The presence of marked cardiovascular disease is a contraindication to the use of atropine The authors have never observed any cardiovascular disturbance in 200 cases treated with atropine The anorexia, with resultant emaciation, at times noted can be combated by the use of insulin At times, a troublesome diarrhea occurs, but it responds to the administration of pepsin and hydrochloric acid The action of atropine on the vegetative nervous system best explains its efficacy in most cases of postencephalitic Parkinson's disease, which the authors believe is due to vagotomy

New Laboratories of Medical School

The demolition of the buildings of the Charité Hospital has been completed Many of the most celebrated medical teachers of France glorified these buildings and there has been much criticism that such important landmarks in the development of medicine during the past three centuries should have been given over to the house wreckers to be replaced by a modern building to be occupied by the laboratories of the Faculté de médecine the only medical school in Paris Some years ago the Rockefeller Foundation offered to contribute three million dollars on the condition that the medical school should leave its present buildings in the Latin quarter and move to a district where lecture halls and laboratories could be in close proximity to one another This offer was refused much to the regret of many graduates of the school who have criticized placing the laboratories about half a mile from the main lecture halls in which the curriculum of the exclusively clinical years is given

Among the most interesting portions of the old Charité Hospital was the amphitheater, in which Courvoisier and later Laënnec taught This has disappeared completely Another room of historic interest is that which the interns on emergency duty used as a gathering place and dining hall Many artists who were friends of the interns and who have since become famous decorated the walls of this *salle de garde*. Fortunately the Assistance publique or administrative body responsible for the free hospitals of the department of the Seine in which Paris is situated have had this historic room reconstructed and medical visitors to Paris can in the future admire the magnificent interior of the *salle de garde* with its invaluable historic associations at the museum of the Assistance publique on the *quai de Tournelle* Those interested in medical history will be well repaid in visiting this landmark.

Complications Following Cesarean Section

In a paper published in the March 15 issue of the *Gazette médicale de France*, P Brault of Rennes reports his observations of forty-nine pregnancies following cesarean section. The low operation was introduced into France by Schikele and later (1923-1924) by Professor Brindeau Brault considers this as the greatest advance in obstetrics since the discovery of asepsis. The high (corporeal) operation has been practically abandoned in favor of the low one The wisdom of this change is amply confirmed by the end results of the high versus the low technique, as the following personal observations of Brault show

UTERINE RUPTURE AFTER HIGH CESAREAN SECTION

Since 1919, Brault has been able to follow seventeen pregnancies (of longer than three months' duration) in patients previously operated by the high cesarean technique. Four uterine ruptures (22 per cent) were observed in the seventeen cases. This percentage would at first seem high, but statistics found in the literature (varying from 2 to 20 per cent) include all types of cesarean operations and not the high alone. In these four rupture cases four different surgeons or obstetricians had operated One of them was a personal case. In the remaining seventeen pregnancies a low operation was necessary in six and a high in seven In eleven of the thirteen cases the condition of the uterine scar was noted In four of the eleven the scar was defective, in two only of thin paper-like consistency Suture of the uterine incision with catgut is more likely to result in faulty union than when one uses silk, as Professor Couvelaire of Paris has shown

LOW (SUPRAPUBIC) CESAREAN SECTION

Brault has not observed a uterine rupture in thirty-two pregnancies occurring in twenty-five women, following the low operation There have been three spontaneous, two forceps and one basiotripsy In the twenty-two cases in which a second (low) operation was performed, no trace of the former (low) incision could be found In three additional cases, a high (second) operation was done, in one case because it was impossible to mobilize the pelvic peritoneum, and in two because Brault deemed that sterilization was indicated. Important adhesions were found in only 11 per cent of the twenty-six low as compared to 36 per cent of seventeen high operations The change, following the low operation, most frequently noted at the second intervention was the elevation of the base of the bladder and obliteration of the vesico-uterine fold. This condition should be borne in mind by the operator if a second low cesarean operation becomes necessary

Carcinomatosis and Fever of Undetermined Origin

An unusual case was reported by Olmer and his associates of Marseilles at the March 27 meeting of the Société médicale des hôpitaux of Paris A man, aged 42, entered the hospital March 28, 1935, on account of persistent fever of undetermined origin. A severe chill followed by profuse perspiration marked the onset, about ten weeks before admission. The fever rose to 102 F and remained so for three weeks The only accompanying symptom had been a severe hematemesis About five weeks before admission a number of small nodules on the trunk and right thigh were noted, which had continued to increase in size, and at the same time cough and marked expectoration appeared An attack of a renal lithiasis had occurred seven years before and a brother had died from gastric and a sister from uterine cancer On examination, enlargement of the spleen and liver and a subicteric tint and leukocytosis were found Nine days after admission, the blood culture was positive for the streptococcus A few days later, an ascites and a para-umbilical nodule appeared Biopsy of a nodule revealed the adrenal as the primary seat of the tumors Death occurred

about eighteen days after admission. At the necropsy a large number of enlarged mediastinal lymph nodes compressing the trachea and esophagus were found, and innumerable small nodules of carcinomatous aspect on the peritoneum and in the parenchyma of the liver, kidneys, pancreas and left lung. The primary tumor was a malignant adenoma of the right adrenal. In Olmer's case the clinical picture was that of a septicemia (fever, large liver and spleen, subicteric tint, positive blood culture and subicteric tint). Similar reported cases of malignant adrenal neoplasia with generalized metastasis and accompanied by fever were cited by the authors. Some authors are of the opinion that the widespread metastasis is the cause of the fever but in Olmer's case, at least there was a concomitant septicemia to explain the fever.

BERLIN

May 13 1936

New Regulation of the Supervisory Medical Consultant Service

The supervisory medical consultant service (*vertrauensärztliche dienst*) was until recently regulated by certain provisions of the national insurance law according to which the insurance societies might permit an investigation by a supervisory medical consultant (*vertrauensarzt*) of the insured's disabilities and the amount of the benefits to be allowed.

The supervisory consultant was however prohibited from infringing on the professional prerogatives of the insurance physician (*kassenarzt*). The insurance society officials were also empowered to appoint either a supervisory consultant or a committee composed of physicians to function in the same capacity. The national physicians and insurance societies' committee had already issued "rules to govern the investigation of the certifications and recommendations of insurance physicians. Special instructions for the supervisory medical consultants were likewise issued by individual sick insurance societies.

Now the supervisory medical consultant service has been regulated anew by a decree of the minister of labor which became effective April 1, 1936. The innovations are of far-reaching significance. They are the fruit of past experience with supervisory medical service and are especially designed to keep pace with the reorganization of the social insurance.

The power to regulate the supervisory medical service has been taken from the individual sick insurance societies and vested in the insurance authorities of the respective states (*landesversicherungsanstalten*). Each insurance authority shall hereafter be composed of three sections: an invalid insurance section, a sick insurance section and a supervisory medical service section.

The director of the last named section must be a physician experienced in supervisory medical service. Among his responsibilities are numbered all questions involving the service together with all pertinent sociomedical problems. This means that he is expected to select the personnel for the supervisory service, keep himself informed as to the condition of the insured, and pass on the necessity for therapeutic substances and apparatus, the advisability of hospitalization and so on. Among the sociomedical functions of the director may be mentioned the inspection of health institutions (hospitals, sanatoriums and the like) and the promotion of prophylactic health services as well as participation in those political activities which involve questions of public health campaigns against common diseases, investigation of facts of genetic import, and similar activities.

A director of supervisory medical service of the state insurance authority does not as a rule, himself engage in the actual routine duties of service, such as investigation of the patients. For the actual performance of the service each state or province

is divided into small districts (*unterbezirken*), within each of which a supervisory service bureau is established. Individual supervisory physicians may be active for a number of sick insurance societies, namely, for all the societies represented within a given subdistrict. There is accordingly an average of one official supervisory consultant for each 25,000 insured persons. In addition, any active physician not connected with the insurance societies who possesses the necessary qualifications may be enrolled by the subdistrict for this service. Specialists too, when it is deemed expedient, may be called in to supplement and assist the supervisory service.

The supervisory medical service stations are to have charge of the necessary diagnostic routines, above all the highly important roentgen procedures. Each station is to possess adequate laboratory facilities. In addition, each station is to have charge of its own assisting personnel. A card is made out for each insured person examined by the supervisory service, and it is especially to be noted whether or not a roentgenogram of the insured has been made and where it is to be found. This is designed to obviate a needless duplication of pictures. If the insured moves his residence from the jurisdiction of a station, the case history and other papers are transferred to the station of proper jurisdiction. In this way an individual record is preserved which contains all pertinent information and which constantly accompanies the insured so long as his dealings with the insurance society continue.

The supervisory medical consultant service now advises and assists the insurance societies by investigating the disabilities of insured persons and recommending the amount of the benefit to which the claimants are entitled. The supervisory physician also may express himself on the necessity of hospitalization or the admittance into a sanatorium or convalescent home of a sick benefit claimant, and in addition he may certify as to the necessity for and value of the therapeutic substances and appliances. The decision will then rest with the insurance holder himself, whose opinion, however, should not run counter to that of the supervisory doctor excepting for reasons of weight. All these activities are carried out not at the instance of the various sick insurance societies but by order of the insurance authorities in the several states. The supervising physician accordingly is under no obligation to the insurance society but is considered an official and employee of the insurance authority.

The new statute expressly states that the supervising physician must not encroach on the professional activities of the insurance physicians. An insurance doctor on the other hand may propose a second examination of the insured by a supervisory physician in order to verify his own diagnosis.

Specific provisions govern the cooperation between supervisory consultants and the attending physicians of hospitals, sanatoriums and convalescent homes. The supervising physician is, first, to obtain the history from the attending physicians, and he should not resort to an examination of the patient unless such a procedure seems absolutely necessary. Such an examination must be undertaken in the presence of the attending physician. The authority of the attending physician must in no way be encroached on nor shall the routine of the institution be unnecessarily disrupted. It is further expressly stipulated that the results of such an examination shall not be discussed with the attending physician in the presence of the patient. The present expansion of the supervisory medical consultant service within institutions for the care of the sick is in accordance with the expressed wish of the national *fürher* of medicine.

This reorganization of the supervisory service is regarded as a most important step forward. The supervising physician, since he now receives his commission from the insurance authority, exerts a sort of indirect influence on the individual

insurance societies Among those who participated in the drafting of the new regulations were the supervising physicians themselves together with the national führer of medicine and the League of Insurance Physicians of Germany

Infant Mortality in Rumania on the Increase

According to Professor Mezinescu of the Bucharest university, infant and child mortality has increased in recent years. Investigations made by Mezinescu revealed that 50 per cent of the infants died before reaching the first year of life, and of those remaining alive only 50 per cent reached the fifth year. In other words, 12,000 infants die in Rumania before reaching 1 year of age. Not only do we lead in this field in the whole of Europe, says Professor Mezinescu, but what is more regrettable, the rate of infant mortality is not as low now as it was fifty years ago. The situation is not much better in towns than in villages. The mortality rate is highest in Bessarabia and the lowest in the county of Ilfov, which comprises the capital city, Bucharest. Mezinescu calls the attention of the government to the fact that large districts comprising from twenty to twenty-five villages have only one doctor.

Sympathetic Ophthalmia, a Seasonal Disease

At a recent meeting of the Oradea Medical Society, Dr. Bela Waldmann, senior ophthalmologist to the Oradea County Hospital, read a paper which was awarded the prize of the society. The subject was the connection between the occurrence of sympathetic ophthalmia and catarrhal disorders of the nose and upper air passages. In his study of the pathogenesis of sympathetic ophthalmia, which appeared in 1933 in the *Wiener medizinische Wochenschrift*, Waldmann expressed the opinion that the etiologic agent of sympathetic ophthalmia migrates into the eye from the accessory nasal sinuses and thence reaches the other eye by way of the optic nerve or through the ciliary nerves. In a study of sixty-nine cases, fifty-three occurred during the influenza period from October to April, while sixteen cases occurred in the warm months from May to September. Waldmann submitted a questionnaire to sixty-eight eye clinics in all parts of the globe, requesting details of all sympathetic ophthalmia cases that were treated during the latter ten years. Ten questionnaires were returned, filled out with scrupulous care, from Baltimore, Berlin, Budapest, Ghiza (Egypt), London, Madras, Manchester, Munich, Stockholm and Vienna. These blanks embodied 124 cases, which, with the sixty-nine cases mentioned totaled 193 cases. The answers submitted showed that three fourths of the cases occurred between October and April. The proportion at the clinic of Professor Meller at Vienna was 7/1. With these data Waldmann feels justified in asserting that sympathetic ophthalmia is a seasonal disturbance. In India it was the rule 1,000 years ago to perform cataract operations in the springtime and to take care that the patients were free from cold. In the book of Halifa it is stated that the Arabians had two special instruments besides those regularly used at cataract operations for the purpose of blowing into the nose various powders for averting catarrhal disorders.

From the statistical reports submitted, Waldmann concluded that sympathetic ophthalmia supervening after cataract operations occur, on an average, in 40 per cent of the cases. Operations with magnets were followed by sympathetic ophthalmia in eight cases. This fact induced Waldmann to propose that in all cases in which one can expect after recovery only a scanty vision of the injured eye or a prospect that the sight will be lost entirely, to remove the eye and in case of the reluctance of the patient rather to leave the metal piece in the eye. The

advantage of preventive enucleation is attested by the Berlin statistics, which, out of twelve cases, embodies only those in which the other eye was unimpaired when the microscopic examination already established the presence of sympathetic ophthalmia. In contrast with these facts, evisceration caused sympathetic inflammation in three instances according to the report of another clinic.

Treatment of Sciatica with Local Anesthesia

Dr. Corneliu Sarbatorescu of Jassy has treated during the last ten years, by means of local anesthesia, thirty-four patients suffering from sciatica. Twenty-three were cured and remained free from recurrences. He makes an alkaline 2 per cent solution of procaine hydrochloride by boiling down to half of its volume a solution consisting of sodium bicarbonate 0.25 Gm., sodium chloride 0.5 Gm., procaine hydrochloride 1 Gm., in 100 cc. of sterilized distilled water. The technic of injection is as follows. A lumbar puncture needle is used, with a glass syringe containing 20 cc. of the solution. The patient sits with the trunk strongly bent forward and with the buttocks projecting backward slightly over the edge of the operating table. The position of the sacrococcygeal membrane, which closes the lower end of the sacral canal, is then identified. Its shape is that of an inverted U or V. The projection formed by the elementary laminae or cornua of the fifth sacral vertebra is first felt for. Between these two cornua is the membrane, which feels elastic and yields slightly to firm pressure. In very fat subjects it may be impossible to find the fontanel. Such cases ought to be excluded at the outset. The needle is pushed perpendicularly through the membrane until it impinges on the anterior bony wall of the sacral canal. The point of the needle is then slightly withdrawn and its direction changes till it runs upward along the canal, pushing up for a distance of 4 to 5 cm. The fluid is then injected slowly, about five minutes being taken to empty the syringe. In a successful case, the injection goes easily and without resistance, no subcutaneous edema is produced, and the patient usually has a feeling of tingling or pressure in both legs. After the injection the patient remains with the trunk propped up and the legs dependent. Any slight feeling of faintness can be checked by a temporary horizontal posture. In from fifteen to twenty minutes all symptoms of sciatica disappear. It is advisable to keep the patient in bed for three or four days afterward.

Dr. Sarbatorescu does not claim that this treatment should be adopted as a routine method in all cases of sciatica. It should be applied when all usual methods fail. A careful diagnosis must first be made. Arthritis and intrapelvic and other local causes must be carefully excluded, and even then, before epidural injections are resorted to, the patient should have a fortnight's energetic treatment with hot applications, diathermy and antineuralgic drugs. The method is specially suitable to cases of root pains in which the distribution extends higher up the buttock than in ordinary sciatica. The technic is admittedly somewhat more difficult than that of injection into the sciatic nerve trunk.

Some Factors in the Spread of Typhoid

At the Oradea Medical Society, Dr. Joan Sandor showed by large charts that the great decrease in the incidence of typhoid in the period from 1925 to 1935 was coincident with the increase in the number of parks and alleys in the city. Greater facilities for the isolation of the sick, the supervision of the milk supply and of other foodstuffs, and the removal of flies and refuse had also contributed. Many cases were imported from the adjacent villages, where public hygiene is much to be desired. Sandor had found lake fish to be responsible for many cases of typhoid. The disease may be acquired also by direct contact, the fingers of the patients' attendants being soiled by excreta, and thus food prepared by them becomes infected.

VAN A OBLF to Miss Opal B Martin both of Spokane, Wash March 30

FRANK VARNUS to Miss Beatrice Brasch, both of Freeport, N Y, June 24

Deaths

Francis Henry Williams ☉ Boston Harvard University Medical School, Boston 1877 Massachusetts Institute of Technology, Boston 1873, since 1879 a practitioner of medicine in Boston, and a pioneer in the development of roentgen ray and radium therapy instructor in materia medica from 1884 to 1885 and materia medica and therapeutics from 1885 to 1886 assistant professor of materia medica and therapeutics from 1886 to 1888 and assistant professor of therapeutics from 1888 to 1891 at his alma mater, member and from 1917 to 1918 president of the Association of American Physicians member of the New England Roentgen Ray Society and the Societe de Radiologie Medicale de France, honorary member of the American Radium Society, American Roentgen Society and the Radiological Society of North America life member since 1882 of the corporation of the Massachusetts Institute of Technology and member of the executive committee for twenty five years visiting physician from 1896 to 1913 and later senior physician to the Boston City Hospital, author of 'The Roentgen Rays in Medicine and Surgery' and 'Radium Treatment of Skin Diseases New Growths, Diseases of the Eye and Tonsils,' and frequent contributor of clinical and research work to the periodical literature, aged 84, died June 22

Imas Pryor Rice ☉ Aurora Ill University of Illinois College of Medicine, Chicago 1913, served during the World War medical director of the Kane County Spring Brook Sanitarium, aged 47 on the staffs of the Sherman Hospital Elgin and St Joseph Mercy Hospital where he died April 23 of a staphylococcal infection, complicated by pneumonia

James Whitney Hall, Chicago Kentucky School of Medicine Louisville, 1890, member of the Illinois State Medical Society, served during the World War for many years a member of the lunacy commission of the Cook County Court, aged 66, died, April 29 in the Illinois Central Hospital, of coronary sclerosis and hypertension

Max Rosenthal, New York, Medizinische Fakultät der Universität Leipzig, Saxony, Germany, 1887 member of the Medical Society of the State of New York president of the medical board and on the staff of the Sydenham Hospital on the staffs of the Bronx Hospital and the Beth David Hospital aged 70, died, April 3

Bernard Lauriston Hardin ☉ Washington D C Columbian University Medical Department Washington 1895 on the consulting staffs of the Garfield Memorial Hospital and the Central Dispensary and Emergency Hospital aged 65 died April 29, of intestinal hemorrhage due to jejunal ulcer and chronic nephritis

Marshall Julius Pierson ☉ Akron Ohio Hahnemann Medical College and Hospital of Philadelphia 1917 served during the World War, on the staffs of the City Hospital and St Thomas Hospital, aged 43 died, April 29 in the Cleveland Clinic, of carcinoma of the stomach and rheumatic heart disease

William Henry Hutchinson, Childersburg, Ala Chattanooga (Tenn) Medical College, 1893, member of the Medical Association of the State of Alabama, past president of the Talladega County Medical Society, aged 69, died, April 17 in a hospital at Sylacauga, of influenza and strangulated hernia

Jessie Elizabeth Bedford Stubbs, Hot Springs, S D College of Physicians and Surgeons, Keokuk, Iowa, 1897 assistant child welfare chairman for the American Legion Auxiliary Department of South Dakota aged 70, died, April 13, in St Mary's Hospital, Rochester, Minn, of carcinoma

Frederick Herbert Nichols, Jamestown, N Y, Syracuse University College of Medicine, 1903, member of the Medical Society of the State of New York, aged 60, died, April 15 in St Joseph's Hospital, Syracuse, of hemolytic streptococcus septicemia, due to an infection sustained while operating

Charles Burr Graves ☉ Gales Ferry, Conn, Harvard University Medical School, Boston, 1886, past president of the Connecticut State Medical Society, on the staffs of the Lawrence and Memorial Associated Hospitals, New London, aged 75, died, April 24, in a sanatorium at Enfield

Joseph I Knoblauch ☉ Metamora Ill Northwestern University Medical School Chicago, 1893, past president of the Woodford County Medical Society, formerly mayor and for many years president of the high school board of education, aged 68, died, April 29, of carcinoma

John Timothy Reynolds, Quincy, Mass, Baltimore Medical College, 1905, member of the Massachusetts Medical Society, on the staff of the Quincy City Hospital, aged 54, died, April 28, in the New England Baptist Hospital, Boston, of carcinoma of the sigmoid

Amy Rilus Robinson Chapman, Franklin, Neb, Grand Rapids (Mich) Medical College, 1900, Lincoln Medical College of Cotner University, 1902 member of the Nebraska State Medical Association, aged 65, died, April 8, of diabetes mellitus and nephritis

Thomas Joseph Ragsdale, Lees Summit, Mo, Marion-Sims College of Medicine St Louis, 1895 member of the Missouri State Medical Association, aged 62 died, April 13 of pulmonary embolism, influenza, chronic myocarditis and cholecystitis

Thomas Crouse Quickel, Gastonia, N C, Tulane University of Louisiana Medical Department, New Orleans 1900 member of the Medical Society of the State of North Carolina, aged 60, died, April 28, of chronic myocarditis and hypertension

Harrison Talmage Smith, Independence, Va Medical College of Virginia, Richmond, 1908, member of the Medical Society of Virginia, for many years a member of the state legislature, aged 52, died suddenly, April 18, of heart disease

Eben Carver Norton, North Chatham, Mass University of Vermont College of Medicine, Burlington, 1885, member of the Massachusetts Medical Society, aged 79, died, April 11, of cerebral hemorrhage, arteriosclerosis and cholelithiasis

Howard Alonzo Wagner ☉ Shawnee, Okla, University of the South Medical Department, Sewanee, 1901 served during the World War, on the staff of the Shawnee Municipal Hospital, aged 60, died April 26, of coronary thrombosis

Sewell Norris Pilchard ☉ Easton, Md Jefferson Medical College of Philadelphia 1910 past president of the Talbot County Medical Society, on the staff of the Emergency Hospital, aged 49, died, April 12, of cerebral hemorrhage

Walter Scott Sowell, Birmingham, Ala, University of Alabama Medical Department, Mobile, 1899, served during the World War aged 61, died, April 27 in the Veterans Administration Facility, Tuscaloosa, of pulmonary tuberculosis

Robert Lee Greer ☉ Oakfield, Tenn, University of Nashville Medical Department, 1890, past president of the Madison County Medical Society, veteran of the Spanish-American War, aged 70, died, April 21 of miliary tuberculosis

Milton Jacobson ☉ Amsterdam, N Y Medical College of the State of South Carolina Charleston, 1919, aged 47, on the staffs of the Montgomery Sanatorium and the Amsterdam City Hospital, where he died, April 29 of cerebellar tumor

Vincent Aloysius Peters ☉ Lees Summit Mo State University of Iowa College of Medicine, Iowa City, 1926, deputy coroner of Jackson County, aged 33, died, April 15, in St Luke's Hospital, Kansas City, of septicemia

J P Prescott, Lake Park Ga, Atlanta Medical College, 1890 member of the Medical Association of Georgia formerly member of the county school board member of the council of Lake Park and mayor aged 70, died April 4

Cecil Durham Stech, Council Bluffs, Iowa, John A. Creighton Medical College Omaha, 1913, aged 46 on the staff of the Mercy Hospital, where she died, April 12, of streptococcal infection, pneumonia and meningitis

Lawrence Arthur Renehan, Darien, Conn. University of Vermont College of Medicine, Burlington, 1922, served during the World War, aged 41, died, April 29, of chronic nephritis, myocarditis and arteriosclerosis

Charles Ramey Thomas, Roodhouse, Ill. St. Louis Medical College, 1887, member of the Illinois State Medical Society, past president of the Greene County Medical Society, aged 72 died suddenly, April 3

Charles W. Fleenor, Bristol, Va., Kentucky School of Medicine, Louisville, 1893, member of the Tennessee State Medical Association, aged 65, died, April 5, in Holston Valley, of coronary thrombosis

Ralph Jackson Raybeck, Pittsburgh, University of Cincinnati College of Medicine, 1919, aged 41, on the staff of the Allegheny General Hospital, where he died April 27, of coronary thrombosis

Harry Edward Anderson, Somersworth, N. H. Medical School of Maine, Portland 1910, past president of the Strafford County Medical Society, served during the World War, aged 49, died, April 22

William Domenico Vento, New York University and Bellevue Hospital Medical College, New York, 1903, aged 57, died, April 15, in the Flower Hospital, of arteriosclerosis and hypertension

Alfred J. Pickering, Huntington, W. Va., Maryland Medical College, Baltimore, 1910, formerly city health officer, aged 61, died, April 17, of cardiorenal disease and cerebral hemorrhage

James Madison Horton, New York, College of Physicians and Surgeons, Baltimore, 1890, member of the Medical Society of the State of New York, aged 71, died, April 21, of lobar pneumonia

Elam Turner Murphy, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908, aged 60, died, April 27, of carcinoma of the prostate

Arthur Edgar Graves, New Waverly, Ind., Rush Medical College, Chicago, 1884, member of the Indiana State Medical Association, aged 79, died, April 27, in the Harper Hospital, Detroit

Silas Franklin Johnson, Los Angeles University of Southern California College of Medicine, Los Angeles, 1894, for many years a medical missionary, aged 70, died April 19

Joseph Anthony Tempesto, Trenton, N. J. Jefferson Medical College of Philadelphia, 1913, member of the Medical Society of New Jersey, aged 45, died April 17, of nephritis

Roy William Allen, Rochester, Minn. State University of Iowa College of Medicine, Iowa City, 1904, aged 55, died April 27, in St. Mary's Hospital, of fracture of the femur

Edward Payson Morrow, Canton, Ohio, Miami Medical College, Cincinnati, 1883, on the staff of the Aultman Hospital, aged 77, died April 14, of coronary arteriosclerosis

William Henry Estes, Lincoln, Ga. University of Georgia Medical Department, Augusta, 1900, formerly member of the state legislature, aged 59, died April 21

Leonard McClintock, Beacon, N. Y. Albany (N. Y.) Medical College, 1897, on the staff of the Highland Hospital, aged 65, died, April 21, of coronary thrombosis

Joseph Camille Eugene Arseneau, Fort William, Ont. Canada, Trinity Medical College, Toronto 1906, aged 58, died, April 6, in Rochester, Minn., of arteriosclerosis

Samuel Fearn Perkins, Los Angeles Vanderbilt University School of Medicine, Nashville, Tenn. 1921, served during the World War, aged 37, died April 20

Roswell W. Comstock, Maumee, Ohio, Detroit College of Medicine, 1901, served during the World War, member of the board of education, aged 60, died April 27

John Ridout, Annapolis, Md. University of the City of New York Medical Department, 1892, aged 68, died April 28, near Ellicott City, of cerebral hemorrhage

Charles W. Beitzel, Norton, Kan. Jefferson Medical College of Philadelphia, 1890, aged 67, died April 30, in a local sanatorium of pulmonary tuberculosis

Frank Stedman Bulkeley, Ayer, Mass., Harvard University Medical School, 1902, aged 57, died, April 19, of hypernephroma with pulmonary metastasis

Joseph L. Price, Sherman, Ky., Kentucky School of Medicine, Louisville, 1884, member of the Kentucky State Medical Association, aged 76, died, April 16

John L. Axtell, Cochran, Pa., Western Reserve University Medical Department, Cleveland, 1882, aged 76, died, April 6, of chronic myocarditis

Lourey L. Quick, New Waverly, Ind., Medical College of Indiana, Indianapolis, 1879, Civil War veteran, aged 89, died April 25, of bronchopneumonia

Frederick Raymond Glover, Mahwah, N. J., University of the City of New York Medical Department, 1885, aged 73, died, April 4, of heart disease

Peyton Page Nottingham, Ferrum, Va., University of the South Medical Department, Sewanee, Tenn., 1904, aged 55, died suddenly, March 10

Lewis Edward Haecker, Hampton, Iowa, Rush Medical College, Chicago, 1894, on the staff of the Lutheran Hospital, aged 72, died, April 18

John F. Cromley, Lamar, Mo., Eclectic College of Physicians and Surgeons, Indianapolis, 1894, aged 79, died April 30, of diabetes mellitus

Austin McMichael, Rockport, Mo., St. Louis Medical College, 1879, member of the Missouri State Medical Association, aged 81, died, April 7

Ragnvald Leland, Kenyon, Minn., University of Minnesota Medical School, Minneapolis, 1895, aged 70, died, April 28, of coronary thrombosis

John Arden Conley, Penn. Yan., N. Y., Eclectic Medical College of the City of New York, 1888, aged 68, died, April 13, of paralysis agitans

George S. Matlock, Carthage, Ark., University of Arkansas School of Medicine, Little Rock, 1900, aged 69, died, April 26, of acute nephritis

Marcell Hartwig, Los Angeles, Medizinische Fakultät der Friedrich-Wilhelms-Universität, Berlin, Prussia, 1873, aged 85, died, April 18

Will K. Johnson, Garnett, Kan., Keokuk (Iowa) Medical College, 1891, aged 79, died, April 30, of chronic cystitis and nephritis

Edward Marcellus Bixby, Oakland, Calif., College of Physicians and Surgeons of San Francisco, 1899, aged 77, died, April 24

William F. C. Hormann, Los Angeles, Bennett College of Eclectic Medicine and Surgery, Chicago, 1903, aged 70, died April 5

Simeon McCausland Metcalf, Los Angeles, Harvard University Medical School, Boston, 1881, aged 78, died, April 28

Robert White Naylor, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1915, aged 46, died, April 16

Florence V. Wall Cheney, Turlock, Calif., California Medical College, San Francisco, 1891, aged 68, died, April 13

Elmer Jones Davis, San Diego, Calif., Rush Medical College, Chicago, 1903, aged 67, died, April 12, of heart disease

John Robert Blackledge, Abbeville, Ala., Medical College of Alabama, Mobile, 1889, aged 80, died, April 28, of senility

Ira Holden Fiske, Pasadena, Calif. (licensed in California in 1920), aged 85, died, April 12, of chronic myocarditis

Elwin Witt Ames, Los Angeles, University Medical College of Kansas City, Mo., 1894, aged 68, died, April 4

George E. Grover, Traverse City, Mich., Saginaw (Mich.) Valley Medical College, 1898, aged 69, died, April 1

William H. Armstrong, Rogersville, Tenn., Louisville (Ky.) Medical College, 1889, aged 74, died, April 9

Joseph Edward Blackshaw, Hemet, Calif., Pulte Medical College, Cincinnati, 1891, aged 81, died, April 18

Walter D. Pelle, Louisville, Ky., Hospital College of Medicine, Louisville, 1889, aged 73, died, April 1

John H. Snively, Justus, Ohio, Medical College of Ohio, Cincinnati, 1891, aged 73, died, March 31

William Stephan, Cincinnati, Medical College of Ohio, Cincinnati, 1896, aged 77, died, April 21

Robert E. Atkinson, Proctorville, Ohio, Columbus Medical College, 1886, aged 84, died, April 2

Bureau of Investigation

LION CROSS HERB TEA OR LION CROSS TEA

A "Wonder of Nature" Declared a Fraud

From New York City the Lion Cross Phar Lion Cross Products Co" and the 'Lio Pharmacy' exploited a cure-all" herb mixture known as Lion Cross Herb Tea or Lion Cross Tea.

According to the memorandum of Mr Karl A. Crowley, Solicitor for the Post Office Department the business was carried on by one Benjamin Eidinger under the above mentioned names Lion Cross Herb Tea or Lion Cross Tea was offered through the mails as a preparation that would "when used as directed" heal those suffering from stomach trouble rheumatism, kidney and liver troubles hardening of the arteries and various other ailments.

Oldest Medical Wonder

Against Stomach Troubles and Rheumatism Acclaimed Best by Latest Tests

Since 1799 thousands of people have regained their normal health after years of suffering from stomach troubles of all types such as constipation, indigestion, gas, and sour stomach which are the basic factors of such maladies as high blood pressure, rheumatism, periodic headaches, pimples on face and body, pains in the back, liver, kidney and bladder disorder, exhaustion, loss of sleep and appetite. Those sufferers have not used any man-made injurious chemicals or drugs of any kind they have only used a remedy made by Nature. This marvelous product grows on the highest mountain peaks where it absorbs all the healing elements and vitamins from the sun to aid HUMANITY in distress.

It is composed of 19 kinds of natural leaves, seeds, berries and flowers scientifically and proportionately mixed and is known as LION CROSS HERB TEA.

LION CROSS HERB TEA tastes delicious, acts wonderfully upon your system and is safe even for children. Prepare it fresh like any ordinary tea and drink a glassful once a day hot or cold.

A one dollar treatment accomplishes WONDERS makes you look and feel like new born. If you are not as yet familiar with the beneficial effects of this natural remedy LION CROSS HERB TEA try it at once and convince yourself. If not satisfactory money refunded to you.

Try it and convince yourself with our money-back guarantee.

One week treatment \$1 00 Six weeks treatment \$5 00

In order to avoid mist in getting the genuine LION CROSS HERB TEA

The advertising matter quoted in the Solicitor's report described this nostrum as a natural wonderful remedy (God's Gift) which had helped hundreds of men, women and children with such unrelated conditions as:

| | | |
|-----------------------|------------------------------|----------------------------|
| Headache | Loss of appetite | Back pains |
| Heartburn | Loss of sleep | Kidney disorders |
| Indigestion | Rheumatism | Arthritis |
| Gas on stomach | Neuralgia | Bladder trouble |
| Female irregularities | Loss of pep in men and women | Pimples and skin eruptions |

The famous quack of seventeenth century England Sarah Cornelius de Heusde, proclaiming her knowledge of the mysteries of nature, new inventions, natural remedies to cure many and divers complaints from the sign of the Red Lion could not have matched the healing qualities proclaimed for the twentieth-century Lion Cross Tea of New York City.

Lion Cross Herb Tea was described as being composed of nineteen varieties of natural flowers, berries, seeds, barks and roots. No ordinary herbs were these. An advertisement translated from a foreign language newspaper introduced during the Post Office Department hearing declared that they grew on the tops of the highest mountain peaks nearest the sun where they absorbed all the healing vitamins and elements which aid to restore the normal functions, thereby bringing health to every organ of your body.

Admittedly, this was good old Mother Nature at her "patent medicine" best, healing headaches, rheumatism, and throwing in for good measure 'the mysterious vitamin 'E' which brings back lost procreative powers to men and women.' Of the nineteen assorted flowers and other parts of plants that this 'shotgun' herb conglomeration was alleged to contain, the shrinking violet was certainly not one. An advertisement of Lion Cross Herb Tea carried by the *Radiant Health Digest*, a publication which, incidentally, calls itself *A National Journal of Food Science*, states "Oldest Medical Wonder—Against Stomach Troubles and Rheumatism—Acclaimed Best by Latest Tests—Since 1799 thousands of people have regained their normal health after years of suffering from stomach trouble of all types such as constipation, indigestion, gas and sour stomach which are the basic factors of such maladies as high blood pressure, rheumatism, periodic headaches, pimples on face and body, pains in the back, liver, kidney and bladder disorders, exhaustion, loss of sleep and appetite. Those sufferers have not used any man-made injurious chemicals or drugs of any kind, they have only used a remedy made by Nature."

Persons who nibbled at such advertising bait received a special typewritten letter. The letterhead on which such letters were written contained what purported to be a coat of arms with the notation 'Est 1799.' A printed circular accompanying the letter proclaimed:

Dear Friend

Do not throw this important message away, but read it to the very end and digest every word of it because this information will save you many dollars and bring HEALTH, HAPPINESS AND LONG LIFE to you and your dear ones.

A specimen of the "Oldest Medical Wonder," when examined by government chemists, was found to consist of a coarsely ground mixture of herbs, as follows:

Senna leaves, corn flowers (Centaurea), fennel seed, caraway seed, anise seed, chamomile flowers, dried orange peel, saffron flowers, licorice root, basswood (tilia) flowers, triticum, sassafras bark, juniper berries, peppermint leaves, lavender flowers, equisetum, mullein leaves and marshmallow root.

This, then, was the drugless life-prolonger, strength-giver and nerve-balancer! The blessing for diabetes and loss of powers" failed utterly to impress the government's medical experts, who declared that practically the only therapeutic effect of the preparation would be laxative and diuretic, with a slight carminative action on the stomach, and that a tea brewed from this mixture and used as directed would not heal persons suffering from all stomach troubles, rheumatism and kidney and liver troubles.

The Solicitor's memorandum to the Postmaster General contained further medical testimony to the effect that no treatment known to the medical profession will cure hardened arteries or restore atrophied elastic fibers, and that it is untrue to represent that the tea brewed from Lion Cross Tea will purify the blood. Except for the resultant effects of habitual laxation through the use of this preparation it will have no effect upon the blood, either in purifying it or in regulating its pressure.

The chief danger from nostrums of this type is that many persons having a fundamental belief in herb mixtures and suffering from serious or chronic ailments may be lulled into a false sense of security.

Although the evidence showed that his concern had been in business only about a year, Eidinger's brazen use of the phrase 'Est 1799' no doubt bolstered the faith of many of the gullible in his nostrums. Indeed, among the complaints received were some from newspapers which, taken in by the apparent age of the firm, had accepted advertising copy for which they had received no pay.

The Solicitor for the Post Office Department, after hearing the evidence, recommended that a fraud order be issued against the Lion Cross Phar, Lion Cross Products Co., Lio Pharmacy, and their officers and agents as such at New York. The Postmaster General under date of April 20, 1936, found the above-mentioned concerns and parties engaged in conducting a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises, and closed the United States mails to them.

Correspondence

CLINICAL EXPERIENCE WITH ERGOTAMINE TARTRATE

To the Editor—Clinical reports of gangrene from the use of ergotamine tartrate recently published in *THE JOURNAL* (May 9, pages 1625 and 1631) merit comment. The case reported by Yater and Cahill emphasizes anew the dangers of ergotism when overdoses are given. The case reported by Gould, Price and Ginsberg in the same issue indicates that even therapeutic doses may lead to serious consequences in special instances.

Since I advocated the use of ergotamine tartrate for the relief of distressing pruritus in jaundice and uremia (*THE JOURNAL*, Nov. 14, 1931, p. 1463) Snell and Keyes have reported its successful use in thirteen cases of jaundice without ill effect (*M. Clin. North America* 16:1455 [May] 1933). My further experience with the drug for this purpose has been with approximately seventy-five persons. Three instances have occurred in which unfavorable side actions might possibly be connected with its use. A man, aged 65, with advanced generalized atherosclerosis, developed a brief attack of tachycardia with precordial distress following a second oral dose of 1 mg. Three subsequent doses caused no complaints. A second person in the same age decade, with obstructive jaundice due to carcinoma, developed a clinical picture simulating coronary artery thrombosis with feeble pulse, cyanosis and fall in systolic blood pressure after four doses had been taken by mouth. The drug was discontinued. The entire clinical picture changed. The patient made a complete recovery from the circulatory disturbance. A jaundiced physician, aged 45, received three doses of ergotamine by mouth for pruritus. The peripheral veins were seen to be collapsed when attempts were made to collect blood samples. Four days later, after 7 mg. of the drug had been taken the pulse was noted to be very feeble and the extremities cold. The systolic blood pressure was not measurable. Bradycardia was persistent. Aside from weakness, the patient was alert, accepted food, and appeared well. Oscillometric readings and skin temperatures were reduced in all extremities. Three days later all objective disturbances had disappeared. The patient recovered from the severe liver degeneration.

Pruritus was relieved in approximately 50 per cent of cases. Resistant cases usually failed of relief by all other measures. The first dose may indicate the prospect of relief. I have found the best method of administration to be as follows: The first dose is given in the evening. If it is beneficial the patient sleeps undisturbed by itching. Three doses are then given by mouth the following day. The drug is discontinued if no relief is obtained and if pains and paresthesias appear in the limbs. If partial relief is obtained, the drug is continued for three more doses. I have seen complete relief following a single dose in a patient with itching lasting several months due to obstructive biliary cirrhosis. The itching was so severe that gloves were worn during sleep.

Ergotamine tartrate has been used over longer periods of time in the treatment of hyperthyroidism and more recently in migraine (Lennox, *W. G. Med. England M. J.* 210:1061 [May 17] 1934). The drug was administered to forty-five patients with this condition without harm. Sometime ago in the course of carefully controlled studies evaluating measures for the treatment of essential hypertension I had occasion to test the effects of the drug in fifteen patients with arterial hypertension in doses of 1 mg. three times daily over a period of four weeks. The patients were warned to discontinue the drug promptly if unfavorable reactions appeared but none occurred. Thus in Lennox's and my experience no mishap occurred in fifty cases with use of the drug over longer periods.

The use of powerful drugs for the relief of distressing clinical symptoms is always fraught with the danger of misuse by the careless and inexperienced despite warning as to their potential toxic effects. This is especially true of medicaments which are effective in milligram doses. Single doses may produce remarkable results. When ineffective, even larger and repeated doses may fail to produce the desired therapeutic response. In the hands of the experienced, the response is gaged from dose to dose and standing orders are not issued.

Dangers from overdosage apply to all drugs. In the case of ergotamine tartrate treatment, therapeutic doses must be given only when strict supervision of the effects of the drug on the patient is possible. Single doses have relieved pruritus in jaundice and attacks of migraine. The use of such a powerful and effective remedy should not be discontinued because reports of gangrene following overdosage appear in the literature or because therapeutic doses prove toxic in a person under special circumstances of advanced atherosclerosis, heart failure, and complicated history of intoxications with barbitals and narcotics. The drug should be continued to be used in conservative dosage by physicians who can evaluate its virtues and dangers.

S. S. LICHTMAN, M.D., New York.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TREATMENT OF ITCH DUE TO VARIOUS CAUSES

To the Editor—For several years I have been called to treat patients afflicted with a severe itching of the skin. The only sign of the malady is a small papule about the size of a pinhead which is either raw or reddish brown and apparently has had its top scratched off. The papules are thinly scattered over the arms, legs and trunk. I have never seen them on the head, face, palms or soles of the feet. The condition affects all ages and both sexes, is apparently contagious and is seen most often in the spring and autumn. Phenolized ointments relieve the itching and after prolonged use the trouble disappears. I should like a prompt remedy if you can so favor me. Please omit name.

M.D. Montana.

ANSWER—The brief description suggests (1) scabies of human or animal origin, (2) pediculosis vestimentorum or bird pediculosis, (3) straw mite itch and (4) trombidiasis—leptus mowers' mite, harvest bug.

1. The typical lesion of scabies is a papulovesicle and not a papule which has "apparently had its top scratched off," though many such scratched lesions may be seen. The burrow of scabies is often difficult to find. Localization of the eruption about the anterior axillary folds, the female breast, the male genitalia, the webs of the fingers and on the buttocks of those who sit at work is a more obvious characteristic. Discovery of the mite, its feces and eggs in a thin slice of epidermis about and including the papulovesicle is the final proof.

Scabies of animal origin is rare and can be eliminated in an epidemic as described.

The treatment of human scabies is the use of Danish ointment for twenty-four hours applying it after a good soaking bath with hot water and soap with care that all the skin from the neck down to the ends of the fingers and toes, is covered by the ointment. Then the patient dons the underwear already worn. In twenty-four hours another good bath is taken with a change of underwear, night clothes, sheets, pillow cases and careful sterilization of all clothing that has been in contact with the skin during the course of the disease. All in the family, whether infested mildly or severely, must be treated at the same time. If Danish ointment fails to clear up the disease (do not mistake secondary dermatitis due to scratching or the irritation of the ointment for scabies) a four day course of the old fashioned formula 10 per cent each of precipitated sulfur, chalk, green soap and Peruvian balsam in petrolatum will probably succeed. The cleanup is the most important part of the treatment.

2 Pedeniosis vestimentorum is manifested by papules topped by blood crusts, blood crusts flit on the skin, scratch marks and secondary dermatitis, most marked in the areas in which the clothing is tight. It is proved by the discovery of the louse in the seams of the clothing. Treatment consists of bathing and sterilization of all clothing.

Bird louse dermatitis resembles scabies occurring as an eruption of discrete papules, though not in the typical preferred areas of scabies, and without burrows or organisms in the skin, on it or in the clothing. The louse retreats after feeding, to the cage or hen house or pigeon house where it may be found in the crevices. Careful cleansing of the hands after care of the birds and removal of their cages from the vicinity of the patient will cure. It is not likely that this would occur in epidemics such as described.

3 Straw itch is caused by a small mite found in the dust from grain or straw. It attacks those who work with grain or who sleep on straw mattresses. The skin lesions are small wheals with central vesicles, on the neck, trunk and limbs. The hands and feet are seldom involved. Larger lesions sometimes occur, vesicles up to 0.3 cm in diameter. Chills and fever, malaise and anorexia may initiate the attack. Itching is more severe at night. A bath, sterilization of the clothing and avoidance of contact with grain or straw dust should cure, for the fever, rest in bed and a mild sedative.

4 The harvest mite, *leptus* is a larva from brick to vermilion red, which becomes active from April to July depending on the latitude and elevation. It is more common in dry summers, is present on grasses and underbrush, and attacks the feet and legs commonly, but it may also be found on the legs or trunk and less on the arms. Women and children are more susceptible than men, perhaps because their legs and feet are less protected. The lesions are follicular papules with the red mite showing in the center. Later they become hemorrhagic. They occur particularly where the clothing is tight enough to stop the travel of the mites at the shoe tops, under garters or at the belt line and may increase in number for a day or so after infestation but there may be a second crop three or four days after the first one. The disease subsides spontaneously in three or four weeks.

The treatment consists of a bath and application of 6 per cent oil of peppermint, rosemary or pine needles in an ointment and a change of clothing, including the garters. The clothing should be sterilized.

SUBCUTANEOUS OXYGEN THERAPY—RASH DUE TO LAMBS WOOL

To the Editor—Inquiries have been made regarding the subcutaneous injection of oxygen to replace the tent or catheter method. I would appreciate a working knowledge of this method of therapy. I have in the past months treated two cases of rash seemingly attributable to genuine lamb's wool fur. In one case only the neck was involved, the person having only that type of fur collar on the coat she was wearing. The other patient a boy of 12 developed a generalized urticarial rash with angioneurotic edema of the scrotum and foreskin after wearing an overcoat lined with this material. Perhaps you could help me in determining the exact dye or irritant causing this reaction. The name genuine lamb's wool seems to be a trade name. In both instances the color of the fur was dark brown. Please omit name.

M D Wisconsin

ANSWER.—The simplest method available for subcutaneous oxygen therapy uses an inflated rubber bag containing from 400 to 500 cc. of oxygen. A large needle on a syringe is inserted into the subcutaneous tissues of the abdominal wall. Suction is made on the syringe to make sure that the needle is not in a vein, and the syringe is removed leaving the needle in place. The rubber bag is connected with the needle by means of rubber tubing and an adapter. A stopcock on the tubing is opened. The bag is gently compressed and the oxygen introduced into the subcutaneous tissue. If the rate of absorption is rapid, 1,000 cc or more may be injected. If the rate of absorption is slow, multiple areas may be used for injection. Injections may be given twice a day. There are two complicated special appliances on the market for this method namely, the "oxygenateur" by Dr. Bayeux of Paris and the Loth apparatus, Utrecht, Netherlands.

The skin manifestations described may be due either to the effect of wool or to the effect of aniline dye or even to the effect of some other antigenic substance not suspected by the patient. If wool is responsible, the more unrefined it is, the more troublesome. A patch test done with undyed wool if negative after twenty-four hours, would indicate the possibility that the aniline dye mentioned is a cause for the skin condition. The variability of the composition of dyes precludes in most cases, tests with them so that a diagnosis by the process of elimination is frequently necessary.

THROMBOPHLEBITIS AFTER CESAREAN SECTION

To the Editor—There seems to be little definite information in the current literature as to when it is safe to start movements, active and passive, of a limb following thrombophlebitis with embolic phenomena. Eight weeks ago, following a massive hemorrhage I elected classic cesarean section in a case of placenta praevia centralis because the child was still viable and I feared that a Braxton Hicks maneuver would destroy the baby. The postoperative course was uneventful and on the fourteenth day there were sudden signs of a pulmonary embolism with infarction. After the use of sedatives for a week the embolic signs and symptoms subsided and the left thigh became swollen and tender along with abdominal distention, sudden hemorrhoids and bladder irritability, which I assumed were due to deep pelvic thrombosis involving the left common iliac vein and the peritreal and prevesical veins. Blood culture was negative. The temperature has remained normal or subnormal but there has been a tachycardia (110/110) for six weeks ever since the first embolic phenomena which I assume is due to a low grade toxemia though the last white cell count is only 6,400 with 74 per cent neutrophils. The treatment to date has been elevation of the limb, dry heat and sedatives. After six weeks of such management (just when the prognosis seemed fair), there was another pulmonary embolism almost as severe as the first. There have been many small showers in the interim. The external saphenous vein is just now becoming involved. What is the present status of citrate solution intravenously? Is surgical ligation of the iliac vein advisable to prevent further emboli? I fear that the thrombosis may extend into the inferior vena cava. When would you chance passive motion? When active motion? Why has no lung abscess developed after all these septic pulmonary emboli? Peham and Amreich recommend six weeks of bed rest after all signs and symptoms are absent. Can you cite other authorities?

M D, Nevada

ANSWER.—There is no inflexible rule for the management of patients with thrombophlebitis. Rest in bed, immobilization and elevation of the affected limb and repeated applications of hot, wet packs are advisable. Ordinarily, active motion may be allowed safely a few days after tenderness to pressure over the vein, systemic fever, and edema have disappeared, provided there is no clinical evidence of extension of the inflammatory lesion. In the usual case of thrombophlebitis the period of confinement of the patient to bed need not exceed two weeks. Long periods of inactivity are not only unnecessary in the usual case but tend to produce neuroses centering on the affected limb, especially when patients were psychopathic or neurasthenic before phlebitis occurred.

The incidence of fatal pulmonary embolism resulting from phlebitis is very small apparently because the inflammatory process has anchored the thrombus to the wall of the vein. However, pulmonary infarction is not uncommon but it is rarely followed by lung abscess. The explanation for this is not clear. Perhaps bacteria, if present in the thrombus, are not viable in the lung. The case cited by the correspondent is unusual. Continued rest in bed, immobilization of the limb, and the application of heat are advisable. The intravenous injection of a solution of sodium citrate is not of recognized value. Ligation of the iliac vein is rarely indicated. The operation itself is additional cause for thrombophlebitis, and there is no good evidence that the ligature would prevent extension of inflammation. Thrombosis of the distal inferior vena cava is not ordinarily serious. Treatment after the inflammation is quiescent, namely, adequate support to prevent edema must be applied to two extremities instead of to one if thrombosis of the vena cava occurs.

RELATIVE EFFICIENCY OF SEDATIVE DRUGS

To the Editor—Can you give me an approximate idea of the relative rapidity of the various commonly used sedatives (given in their average dose) and also their relative duration of action? It is my impression that, in general, the rapidity of action is inversely proportional to the duration of the effect. I am interested chiefly in the barbituric acid derivatives but I would also like to know how other sedatives such as bromide chloral and bromural compare with them. Kindly omit name.

M D Connecticut

ANSWER.—The barbituric acid derivatives may be divided into those of prolonged and those with short action. Thus pentobarbital sodium and picrotoxin belong to the agents of relatively short action (from three to six hours) and phenobarbital and barbital to those of enduring action (from six to eight hours), with amylal and cyclohexenyl ethyl barbituric acid ranging somewhere between these. The proposition that the more rapid the onset of action the shorter the effect may seem to be borne out by the rapid onset of the action of most of the rapidly acting barbiturates, e. g., the fact that the action of pentobarbital and cyclohexenyl ethyl barbituric acid sets in earlier than with most of the other barbiturates, the effect of which is in general secured within half to three quarters of an hour. This relation is, however, not essential, as the onset of action depends on rapidity of absorption, which in turn depends on a water and lipid solubility factor as well as possible dissociations in the organism. The duration of the effect, on the

other hand, depends on the rapidity of destruction in and elimination from the organism. In the agent of brief action a destruction occurs so rapidly that it is completed over night, while barbitol is eliminated slowly and largely unchanged, so that with full doses there is often a certain degree of depression experienced the next day and there is liability to cumulative action. The hypnotics of short duration may initiate a sleep which then continues throughout the night even though the action of the narcotic itself has ceased. If the patient awakens too early, a hypnotic of more prolonged action is indicated. Chloral hydrate acts rapidly, within fifteen minutes, so that it may be given just as the patient goes to bed, while the barbiturates are better given from half to three quarters of an hour before bedtime. As chloral hydrate in moderate dosage is rapidly eliminated, it does not produce sleepiness the next day. Bromide action is slow in onset. It is not a true hypnotic. It merely lessens reflex excitability and restlessness and thus favors sleep but does not force it on the individual as do the true hypnotics. As it is slowly eliminated, its effects are rather enduring. Bromural is also a sedative rather than a narcotic, it produces sedation and slight sleepiness within half an hour and thus may suffice to induce sleep in mild cases of insomnia. Its real action continues for about three to five hours, but, as before stated, sleep once induced may continue longer.

EFFECTS OF OVARECTOMY

To the Editor—Please advise me what the untoward symptoms are following the removal of both ovaries. Is intermittent sweating marked one of them? If so, what would be the suggested dose of theelin in oil? What would be the interval and the probable duration of such treatment? Please use initials only.

M D Alabama

ANSWER—In a woman of menstruating age, removal of both ovaries produces a surgical menopause with the possibility of having menopausal symptoms of varying degree. The intermittent sweating, hot and cold flashes and feeling of tiredness may in some cases be quite marked, while in other cases they may be slight or even absent.

It has been found that treatment with estrogenic substance together with the oral administration of bromides acts in many instances to alleviate or completely relieve the annoying symptoms. The estrogenic substance is best used in an oil solution, 2,000 rat units per cubic centimeter administered in deep intramuscular injections once a week. Any of the ethically produced and standardized products may be used. It may be necessary to carry on such treatments over a period of many months or until such a time as the menopause is well established and the vasomotor disturbances accompanying its onset have subsided. The bromides act to cut down on the patient's nervous irritability and to decrease the reaction to the vasomotor stimuli.

It must be remembered that it is possible for the patient to have conditions not associated with the genital tract which may be responsible for the discomfort or add to it. Because of this, hypertension, cardiac disease, renal insufficiency and blood dyscrasias must be ruled out before one can extend hope for improvement by hormone replacement therapy plus the use of sedatives.

GAUZE SPONGE IN PERITONEAL CAVITY

To the Editor—As a search through standard textbooks and reference works on surgery has been unsatisfactory would you kindly inform me regarding the symptoms caused by a gauze sponge left in the peritoneal cavity? Could such a foreign body in this location give no signs or symptoms for a period as long as three months postoperatively? Might three sponges be lost in the peritoneal cavity of a moderately obese woman and give no signs or symptoms? Please omit name.

M D Minnesota.

ANSWER—In most instances in which sponges have been removed after being left in the abdomen the symptoms were the result of suppuration.

It would seem impossible to differentiate irritation by a foreign body from localized peritonitis following operation. Pressure symptoms that not infrequently affect the bladder are usually due in either instance to an abscess. The chief differentiating symptoms are that in postoperative peritonitis there is acute inflammation with tympanites, while with a foreign body there may be few or no symptoms until secondary infection develops.

Provided suppuration does not develop, the early symptoms of irritation and pressure which might simulate those after a laparotomy could subside either completely or partially. In the latter instance any persisting symptoms might simulate adhesions which might follow a low grade infection that had subsided.

In the event of infection developing about a gauze sponge or foreign body, suppuration would persist until the foreign body had passed out or was removed at a subsequent operation.

One or even three small sponges might remain in the abdomen three months or longer with no symptoms, provided their size did not produce pressure symptoms and they did not become secondarily infected.

In the course of several hundred operations on animals it has been observed on several occasions in which sterile gauze sponges were left at a previous operation weeks or months before that these sponges were completely surrounded by omentum with no suppuration or surrounding adhesions. There were no symptoms due to the presence of these walled-off sponges. It is possible that animals may tolerate foreign material better than human beings. No doubt the size of the sponge is of importance as well as the size of the omentum that may be available for surrounding it and preventing contact with the intestinal wall, through which infection may come.

In the presence of a large omentum there would be a better chance for it to wall off a gauze sponge without the development of secondary infection or other symptoms.

INJURY TO ROOF OF MOUTH IN REMOVING TOOTH

To the Editor—A woman, aged 23 single suffering pain in a tooth due to a cavity, saw her dentist. He noted the cavity in the left molar and advised its removal. This was done. There was no abscess or other evidence of infection on this tooth when removed. As the dentist was removing the tooth the patient noticed a sharp pain in the roof of her mouth. She called his attention to this. He told her there was a slight laceration of the roof of the mouth whether due to scratching with the tooth as he was removing it or to the instrument (dental forceps) he did not know. This occurred Aug 14 1935. I was called that evening and noted the laceration extending over the right posterior palate, which the patient said was painful. I advised hot irrigations. The dentist was consulted. He said that rinsing the mouth would be sufficient. This was done August 17. The girl was unable to open her mouth. She suffered pain in the roof of the mouth and in her neck. I again advised hot irrigations and also fomentations to the neck. On the 19th, at the request of the dentist, she used antiphiogistine externally. That night the pain was intense. A hypodermic did no good. No improvement had occurred on the 20th. She had a temperature of 103.2 F. At 7 p. m. August 22 she had a severe chill. I removed her to the hospital and gave a citrated blood transfusion. For two days she had a septic temperature. Drainage then began from her mouth. The fever subsided by lysis. Drainage coming from the roof of the mouth continued for nearly two weeks. The question arose as to how an abscess could develop on the palate. It was generally believed to be due to the trauma of the laceration. However the dentist says that the drainage from the tooth socket moved backward up the pillars and fauces to the palate. Does this occur? My impression as to drainage is in a direction opposite to this the drainage being into the submaxillary and deep cervical glands. Kindly omit name.

M D Coosuechent.

ANSWER—It would seem unlikely that the acute infection described was due to any other cause than the injury to the roof of the mouth and the bacterial invasion through this portal of entry. The normal course of lymph drainage from both of the regions mentioned is toward the upper deep cervical lymph nodes, from the palate region by way of nodes along the internal maxillary artery and from the lower molar zone by way of submaxillary channels. Only in cases of blocked drainage can the lymph flow be reversed. In this case the first evidences of inflammation were in the palate, and extension was along the normal paths for drainage without involvement of the extraction site and the regions next in line. Consequently there is no reason to believe that drainage was blocked and that infection extended from the extraction socket to the roof of the mouth by way of the pillars and fauces.

OPERATIONS FOR OCCLUSION OF FALLOPIAN TUBES

To the Editor—My daughter in law is 30 years old five years ago she gave birth to a son. Everything was normal. She has had no children since. Examination shows occlusion of both tubes near the fimbriated ends. She is in perfect health and desires more children. Unfortunately an operation seems the only way out. My son was home from Ohio and consulted me about it but I am not in a position to give him any advice. I want therefore, to ask you. What percentage of these operations is successful? Can you give me the names of any surgeons in Cleveland Cincinnati Pittsburgh or other cities in that neighborhood where this work has been successfully done?

M D Minnesota.

ANSWER—Operations for relief of sterility ascribable to occlusion of the fallopian tubes are satisfactory in not more than one third of the cases. Obstructions limited to the fimbriated ends of the tubes offer a somewhat more favorable prognosis.

Before resorting to surgery the fertility of the husband should be determined, despite the fact that he is the father of a healthy child 5 years of age. He should also be questioned relative to the possibility of having acquired a gonorrheal infection the most common cause of bilateral tubal occlusion.

Most authorities advocate radiography of the tubes prior to operation, although some are content with a Rubin test. Instillation of iodized oil and radiography give more detailed information than a Rubin test, but some hesitate to use it as a routine procedure because of the possibility of lighting up an infection.

It is inappropriate to recommend in *THE JOURNAL* the names of any individuals. Through the leading hospitals and medical schools one can readily obtain the names of competent gynecologists.

FASCIA STAIN

To the Editor—I need to know of a stain that will stain fascia only. This stain should not stain muscle, fat, nerve or anything but fascia.

T. E. ZINKAN, M.D., San Jose, Calif.

ANSWER—There is no known stain that will stain fascia only. There are several stains that will differentiate connective tissue or elastic fibers from other structures. The most useful are the following:

A Mallory connective tissue stain. The connective tissue stains deep blue, nuclei red.

1. Remove paraffin with xylene
2. Absolute alcohol
3. 95 per cent alcohol
4. 80 per cent alcohol
5. Wash in water
6. Zenker's solution twenty-four hours (if not Zenker fixed material)
7. Aqueous solution of iodine (Lugol's solution) fifteen minutes
8. Decolorize with 5 per cent solution of sodium thiosulfate for thirty seconds
9. Wash thoroughly with distilled water
10. 0.5 per cent aqueous solution of acid fuchsin two minutes
11. Wash in distilled water
12. 1 per cent phosphomolybdic acid nine minutes
13. Transfer directly to Mallory's stain from two to four minutes
14. Wash with 95 per cent alcohol
15. Dehydrate with several changes of 95 per cent and absolute alcohol
16. Clear in xylene
17. Mount in balsam

B Van Gieson's stain for connective tissue. The connective tissue is deep red, the nuclei are black.

1. Fixation in almost any fixative
2. Remove paraffin and so on, as usual
3. Mix Heidenhain's iron hematoxylin solution 1 with equal parts of No. 2. Stain from four to five minutes
4. Wash in distilled water
5. Van Gieson's picric acid fuchsin one minute
6. Dehydrate
7. Clear in xylene
8. Mount in balsam

C Weigert's elastic tissue stain. Elastic tissues are from dark blue to black, the nuclei stained lightly with carmine. Formaldehyde fixation is preferred.

1. Remove paraffin with xylene
2. Absolute alcohol
3. 95 per cent alcohol
4. 80 per cent alcohol
5. Distilled water
6. Place in 1 per cent safranin for twenty-four hours or in an autoclave from three to five hours
7. Wash in absolute alcohol
8. Elastic stain from five to twenty minutes (use microscope)
9. Rinse several times in absolute alcohol
10. Clear in xylene and mount in balsam

STREPTOCOCCUS CARRIER AND OBSTETRICS

To the Editor—A helper in a hospital constantly shows streptococcus in smears from her throat. A culture sent to the state laboratory was reported staphylococcus only. She had her tonsils thoroughly removed a few years ago. Would you consider it dangerous to have her working around the obstetric department? What can be done to clear up the condition? She has been given streptococcus serum and has been using mild antiseptics in her throat. Please omit name.

M.D. Minnesota

ANSWER—If streptococci persist in the helper's throat in spite of local and general treatment, it is best to have her stay away from the obstetric department. There is always the possibility that at some time or other the streptococci may become virulent, especially during the winter months, and the helper may then become a direct cause of infection. If the helper should constantly wear a mask which would cover not only her mouth but also her nose, the risk of infection would be reduced considerably but there would still be the danger of contamination from her hands. The risk should not be taken, especially when it ought to be possible to employ the helper in some kind of work in a part of the hospital where there is no danger of infection.

TUBERCULOUS LYMPHADENITIS

To the Editor—A woman aged 30, married, with two children, weighs 155 pounds (70 Kg.) appears healthy and has no complaints except swellings on the side of the neck. She had swollen glands in the right cervical region five years ago resulting in two abscesses which required incision and took about four months to heal. During the past five years the glands have become enlarged occasionally but have not resulted in abscesses. In January 1935 a swollen gland developed on the left side of the neck which required incision and which healed in five months. In August 1935 swelling developed on the right side, which was incised and is still not healed but has a small scab which on removal disclosed a granulating area with some discharge. At this time December 1935, she has two other swellings on the right side of the neck which are not very tender, are apparently adherent to the skin and are quite movable. Blood examination reveals 74 per cent hemoglobin, 3,900,000 erythrocytes, 5,600 leukocytes, 33 per cent neutrophils, 1 per cent myelocytes, 50 per cent lymphocytes, 8 per cent mononuclears, 6 per cent eosinophils, 3 per cent basophils, 11 per cent staff cells, 21 per cent segmented forms. Examination of the urine gives negative results. The blood Wassermann reaction is negative. The tuberculin test with 0.001 cc. of old tuberculin is positive. The basal metabolism is 16 per cent. Roentgen examination of the teeth and of the chest gave negative results. During the past four months the patient has been advised to rest more frequently, to drink cod liver oil and milk and to take calcium phosphate one tablet twice daily. She has gained 10 pounds (4.5 Kg.) on this regimen yet the swollen glands have come again. Is there anything else that can be advised? I have assumed a diagnosis of tuberculous adenitis. Can it be anything else? I have now advised general ultraviolet therapy twice weekly, also local heliotherapy. What is the opinion regarding these measures? Please omit name.

M.D., New York

ANSWER—The clinical history and the laboratory examinations are both typical of a tuberculous lymphadenitis. There is one other possibility and that is a superimposed Hodgkin's disease. This should be determined by a biopsy with a pathologic and bacteriologic examination.

If it is found to be only tuberculosis, the treatment should be aimed at a progressive tuberculous lymphadenitis: relative rest periods, removal from the responsibility of care of the children and household, and a balanced and adequate diet, including vitamins. This has apparently been done. Ultraviolet therapy administered in progressive dosage is indicated as well as progressively administered heliotherapy, if there is adequate sunlight. The latter need not be strictly local. The trouble with sunlight is its inconstancy. In most parts of the United States there is so much fluctuation of light that the advantages from such methods are little or nil. Measured ultraviolet radiation is much to be preferred, because it can be measured and given in accurate and proper dosage.

TREATMENT OF EARLY SYPHILIS

To the Editor—Printed in a copy of *Modern Medicine* in December 1934 was Friedman's Ready Reference tables for the treatment of early syphilis. In case you have no reference it goes as follows: one week of neoarsphenamine 4.5 Gm. and 0.6 Gm., second week neoarsphenamine 0.6 Gm., third week, 0.1 Gm. of a bismuth compound and neoarsphenamine 0.6 Gm. End of course one seronegative primary syphilis. From the fourth to the eighth week a bismuth compound and neoarsphenamine. From the ninth to the seventeenth week, a bismuth compound. So it goes on in alternate nonrest periods courses through course five. What I should like to know is whether this may be considered authoritative? Second the entire course of treatments would take eighty-one weeks. Is less than this justifiable? Please omit name.

M.D. Virginia

ANSWER—The article by H. L. Friedman entitled "Early Syphilis—Diagnosis and Treatment Graphically Represented" was published also in *Colorado Medicine* (31:353 [Oct.] 1934). The course of treatment outlined by Dr. Friedman may be regarded as adequate. It differs in certain minor respects from the standard treatment procedure suggested by the Cooperative Clinical Group (*THE JOURNAL*, April 21, 1934, p. 1267). These differences are as follows:

1. The dosage of neoarsphenamine should be from 0.45 to 0.6 Gm. for women and from 0.6 to 0.75 Gm. for men. Nothing is gained and something probably is lost by starting treatment with smaller doses than these. There is no adequate reason for starting the treatment of early secondary syphilis with bismuth compounds. In all stages of early syphilis, treatment is more properly initiated with an arsphenamine.

2. The preparation of bismuth utilized by Dr. Friedman is not mentioned, and the dosage suggested (from 0.1 to 0.15 Gm.) is a trifle small. An adequate dose of the preferable insoluble bismuth salicylate is 0.2 Gm.

3. The treatment of seropositive primary syphilis should be at least as long as that of early secondary syphilis.

4. The total duration of treatment, as outlined by the group, is approximately ten weeks shorter than that suggested by Dr. Friedman.

5 The after-care of treated patients should not cease with a three to five year observation period but should be prolonged throughout the patient's lifetime.

The essential feature of the treatment plan suggested by Dr Friedman is, however, the same as that outlined by the Cooperative Clinical Group, namely, that the treatment of early syphilis shall be continuous throughout, with no interpolated rest periods of any sort

EDEMA IN DIABETES

To the Editor—A woman aged 42 who has had diabetes for four years but has been under management for only one year complains of edema of the lower extremities during the day. This disappears at night but appears in the hands, arms and face in the morning. She states that her eyes are swollen so badly that she can hardly open them at times. Last Christmas she was in the hospital for diabetic coma. During the past summer she developed an infection in her thigh as the result of insulin administration. Since this episode she has had this edema. The output of urine is diminished. She has menstruated only once in the last six months in October. At this time edema disappeared for about ten days. She is taking about 30 units of insulin daily and showing some sugar but she was sugar free this fall and the edema was unaffected. She is on a diet of 65 Gm of protein, 135 of fat and 85 of carbohydrate. No urinary cardiorespiratory digestive or nervous symptoms are apparent. The physical diagnosis and examination are essentially negative except for marked pitting edema from the mid thigh down on both extremities. Hemoglobin is 70 per cent the urine contains 0.2 per cent of sugar but no albumin. Can this be a nutritional edema from mineral deficiency? If not what are other possibilities? What treatment is there? Please omit name

M D Iowa

ANSWER—The fact that this edema affects not only the legs but also the arms and the face and that the infection mentioned developed in only one thigh makes it unlikely that the infection is responsible for the edema. The absence of menstruation might be due to an early menopause but also suggests that dietary deficiency is a factor in this edema. The present diet may be inadequate in calories but seems to be supplied with enough protein and therefore does not seem responsible for the trouble. Mineral deficiencies rarely if ever cause such edema. Essential for the diagnosis would be a determination of the total proteins of the blood plasma as well as the relative amount of serum albumin and serum globulin. A low protein content of the blood plasma, particularly a low albumin content, would support the diagnosis of nutritional edema.

HIGH VITAMIN ACID ASH DIETS IN URINARY INFECTION

To the Editor—What is the rationale of the high vitamin acid ash diet in infections of the urinary tract? Why is sodium chloride so strictly prohibited in this diet? Should the diet consist exclusively of foods that have acid ash or may the diet be supplemented by basic or neutral foods? Isn't it an incongruity that everything that is prepared with salt is taboo? The diet lists allow American cheese Cheddar cheese and frankfurters. All these foods have a large percentage of salt. Where can I look up this subject in detail? Where am I to get a complete table of foods generally consumed as to their ash reaction whether acid basic or neutral?

ROBERT FISHER M.D. New York

ANSWER—The rationale of the high vitamin A acid ash diet in infections of the urinary tract depends on the production of an acid urine. The inhibition of the growth of bacilli by acid urine dates to the work of Shohl and Janney in 1917 (*J. Urol.* 1:211 [April] 1917). The contraindication for the inclusion of much sodium chloride in these diets is discussed by Charles Higgins of Cleveland. His most recent report on the subject is in *Surgical Clinics of North America* 15:923 (Aug.) 1935. Lists of acid and basic foods can be found in "The Chemistry of Food and Nutrition" by Sherman edition 4, New York: Macmillan Company, 1932, and in "Nutrition and Diet in Health and Disease" by J. S. McLester, Philadelphia and London, W. B. Saunders Company, 1927.

CARCINOMA OF FUNDUS OF BLADDER

To the Editor—I have a patient who has a carcinoma of the fundus of the bladder. This growth is 5 by 3 cm in diameter and is a hard mass. The bladder capacity is 2½ ounces. The general condition of the patient is good. Is the prognosis of the patient better by treating him with radium or better by transplanting the ureters into the bowels and removing the bladder? Please omit name.

M D Tennessee

ANSWER—There still is a good deal of diversity of opinion regarding treatment of carcinoma of the fundus of the bladder. Suprapubic cystostomy with surgical diathermy is the procedure in a great many clinics. Others are of the opinion that the implantation of radium with the cystoscope is the method of elimination. In the third group one finds those who believe in cystostomy and here one finds diversity of opinion on the

one hand are those who believe that the ureter should be implanted into the bowel, and in the other group one finds men who believe that the ureter should be transplanted into the skin and catheters inserted into the ureter.

INTRAVENOUS ALCOHOL AS NONSPECIFIC PROTEIN THERAPY

To the Editor—Would you send me indications contraindications, dangers and the technic of intravenous alcohol preparations in the treatment of suppurating fetid disorders especially of the lungs? I find many references, all of foreign origin as for example "Intravenous Alcohol Preparations in Treatment of Suppurating Fetid Disorders" (*Mit. Klin.* 30:538-543 [April 20] 1934). I find it referred to as the Lander method 33¼ per cent alcohol. RAYMOND L. EVANS M.D., Sayre, Pa.

ANSWER—One must look on intravenous injection of alcohol (33¼ per cent) as a form of nonspecific proteotherapy the alcohol acting as a "denaturant" of the blood protein with which it comes in contact in sufficient concentration. Its indications may therefore be conceived quite broadly, as by Breuer and Aron (*Wien med. Wchnschr.* 85:868 [Aug. 3] 1935), who advocate it also in diverse other infectious diseases, such as erysipelas, diphtheria, tonsillitis, scarlet fever, furuncles and phlegmons. Debility so extreme that the patient might not survive the protein shock constitutes the chief contraindication. Cardiac depression is the chief danger, which may be possibly antagonized, when encountered, by intravenous injection of 20 cc. of 33 per cent dextrose and by the usual heart stimulants. The technic requires drawing the alcohol into the syringe without the needle and testing the patency of the needle with sterile physiologic solution of sodium chloride rather than with alcohol. The injection should not be started until blood wells into the needle and should then be made extremely slowly, blood being drawn into the syringe from time to time.

BLOOD VESSELS IN FAT

To the Editor—In a speech made in Washington in 1924 Dr K. H. Beall stated that there are about 4500 feet of blood vessels in each pound of human fat. This speech was published in the *Southern Medical Journal* of May 1924 under the head "The Parasitism of Fat." So far I have been unable to discover any facts that tend to prove or disprove Dr Beall's statement and I am wondering whether you can shed any light on the subject.

HARRY H. FIELD New York

ANSWER—The length of the blood vessels in one pound of fat, such as exists in the human superficial fascia, has not been definitely worked out. The length of blood vessels in one pound of human skeletal muscle has, however, been estimated approximately (Krogh, *Anatomy and Physiology of Capillaries*, 1924, p. 10). Krogh's calculations would indicate that in one pound of muscle (human) the length of blood capillaries is approximately 568 miles.

Vascularity of fat is great, though apparently less than that of muscle. In a kitten in which the blood vessels were injected with carmine gelatin and preparations made in identical manner of muscle and of fat from the mammary gland, the blood vessels in the muscle tissue were apparently five times as numerous as the capillaries in the fatty tissue (This is a rough approximation). Assuming that the same proportion exists in the human animal the length of capillaries in one pound of fatty tissue would be a little over 100 miles.

ETIOLOGY OF PALPITATION

To the Editor—Is the onset of palpitation (pulse average 84) following (1) small amounts of alcohol (2) smoking a cigaret (3) slight effort (4) ephedrine and epinephrine used as sprays (5) one-half grain (0.03 Gm.) of thyroid extract ingested in a person aged 30 with no other physical sign or laboratory finding of heart disease evidence of occult heart disease? The palpitation is visible and easily felt and lasts from minutes to hours. During this period there is frequent sighing and marked weakness. Omit name place.

M D New York

ANSWER—Palpitation is the consciousness of the heart's action, whether fast or slow, regular or irregular. It may be a disagreeable sensation and in a nervous or sensitive person become quite distressing. The sensation is one of pounding or thumping but sometimes there may be fear, weakness, pain or even dyspnea.

The commonest cause of palpitation is a simple increase in the rate and force of the heart beat under the influence of exertion or excitement. Fatigue, infection, neurocirculatory asthenia, thyrotoxicosis, and in some persons tea, coffee, tobacco, alcohol, epinephrine or ephedrine or procaine hydrochloride for local anesthesia frequently cause the heart to beat harder and faster. Palpitation is especially likely to occur during convalescence from illness that has no organic effect on the heart.

There are other causes of palpitation, such as the abnormal tachycardia, paroxysmal tachycardia, auricular fibrillation or auricular flutter. In a patient aged 30 with no other physical signs or laboratory signs of heart disease palpitation does not itself indicate the presence of any disease. A basal metabolic rate determination would be advisable to exclude thyrotoxicosis. An electrocardiogram during the attack will reveal the presence of any abnormal tachycardia. Alcohol, tobacco, coffee, ephedrine and thyroid extract may cause palpitation in healthy persons without indicating the presence of organic heart disease.

REACTION TO SULFARSPIHENAMINE IN SYPHILIS

To the Editor—A white woman aged 42 weighing 205 pounds (93 kg.) was found to have a 4 plus Wassermann reaction. This was discovered when the patient presented herself with an ulcer in her nose. I immediately put her on one weekly injection each of bismuth salicylate intramuscularly and sulfarsphenamine 0.4 Gm. also intramuscularly. Owing to the patient's overweight intravenous injections are difficult. After three weeks' treatment the nasal ulcer healed but the patient began to have attacks of nausea and gagging immediately following the sulfarsphenamine injections. These attacks last for half an hour after ward she feels well and has no complaints. What is the cause of these attacks? Is faulty technique to blame? I follow exactly the directions given. What can be done to prevent these attacks? Should the injections be discontinued? The patient begins to dread the sulfarsphenamine and wishes to be treated only by bismuth compounds which I do not consider sufficient. So far she has received seven injections of each chemical.

M D New Jersey

ANSWER—The nausea and gagging that appear following the intramuscular injection of sulfarsphenamine may be attributable to a psychic effect, a nitritoid reaction or one of the mild gastro-intestinal upsets that follow injections of arsenic. As a rule, intramuscular injections do not produce pronounced psychic reactions. The nitritoid reactions from intramuscular injections of sulfarsphenamine usually appear four or more hours after the injection, although such reactions have been reported as appearing immediately or up to half an hour after the injection. The nausea and gagging that this patient encountered is probably the result of an idiosyncrasy to the drug. Accordingly, faulty technique is probably not a factor. It would seem advisable to try another intramuscular preparation such as bismuth arsphenamine sulfonate, bearing in mind that this contains sulfarsphenamine, and if a reaction is noted following it, further use of intramuscular preparations would not seem warranted. In view of the difficulty of intravenous injections it would probably be necessary to limit the treatment to the use of intramuscular injections of a bismuth preparation giving the patient probably twenty injections to a course at least twice a year for a minimum of three years.

IRON PRESCRIPTION NOT RELATED TO CARIES

To the Editor—In March 1935 I prescribed this treatment for a patient with secondary anemia:

R Ferr et ammonii citratis
Syrupi auranti
Aqua q s

ad 8
℥ss

Sig Two teaspoonfuls in a little water after meals

This was refilled several times. During the following summer and fall caries of the teeth developed requiring extensive dental repairs. The patient is firmly convinced and her dentist supports her in this conviction that the iron prescription was responsible for the damaged teeth. Please inform me whether there is any evidence to support such a theory of tooth decay.

M D New York

ANSWER—The iron prescription referred to being free from corrosive acid, could not possibly have produced dental caries. It must have been due to some other cause.

SEPTIC SORE THROAT AND SCARLET FEVER

To the Editor—For the past two years there has been a long drawn out epidemic of scarlet fever in this region. Many cases have been and still are being reported as septic sore throat and I must admit that I find nothing in my books that shows any possibility of mistaking the two diseases. These cases of septic sore throat show a rash over the body which in my opinion is scarlet fever. What I wish to learn is whether or not septic sore throat gives a generalized skin rash and also what the differential diagnostic points are of each disease. I would prefer having my name omitted.

M D Wyoming

ANSWER—In epidemics of septic sore throat, occasional rashes are reported. These are usually erysipelas but transient generalized rashes may occur. Dr D J Davis has shown that septic sore throat is caused by a hemolytic streptococcus which produces a toxin that is weak in comparison to scarlet fever toxin and is not neutralized by scarlet fever antitoxin. In case a generalized rash appears, the diagnosis may be made

by means of a blanching test with scarlet fever antitoxin. In selecting antitoxin for this purpose it is important to choose a preparation that contains no erysipelas or septic sore throat antitoxin. Some of the commercial preparations are taken from horses which have been immunized with more than one kind of hemolytic streptococcus toxin, so that the serum contains more than one kind of antitoxin, although at present it is not so labeled.

USE OF SNAKE VENOM IN CARCINOMA AND IN HEMORRHAGE

To the Editor—Will you kindly forward to me what information you have as to the use of snake venom in the control of pain as in carcinoma when morphine has lost its control and again the use in controlling hemorrhage as in prostate or bladder hemorrhage.

M D Illinois

ANSWER—There is no evidence that snake venom is of value in the control of pain associated with cancer.

Snake venom has been used in idiopathic bleeding of various kinds. It is apparently effective in nasal bleeding in cases with actual local vascular changes such as are found in Osler's disease and even in the presence of erosions (Peck, S M, and Rosenthal, Nathan. Observations on the Effect of Moccasin Snake Venom in Hemorrhagic Conditions, *THE JOURNAL*, (March 30 1935, p 1066). It has also been used in cases of gastric and urinary hemorrhage by Dr Peck with apparently beneficial results in a number of cases. Since it can be given in daily doses of 1 cc. without any harmful effects, there is no contraindication to its use in the type of case inquired about. The initial dose should be 0.5 cc. of the 1:3,000 dilution (supplied by the Lederle Laboratories), rapidly increased to a maximum dose of 1 cc. daily until the hemorrhage has been controlled. After that the number of injections per week can be reduced until the proper maintenance dose is reached and the proper therapeutic response obtained. A detailed description of doses is given in the report mentioned.

TREATMENT OF HYPERHYDROSIS

To the Editor—I have a patient whose chief complaint is of extremely profuse and debilitating night sweats. She has at the present time practically no other complaint. Several months ago she underwent a pelvic operation with a rather stormy postoperative course. One ovary was removed but one remains and her endocrine system is otherwise in good order so far as one can tell. Her blood pressure is normal. Her heart function is good. She does not have any fever, is in a fairly good state of nutrition and is more or less actively engaged as a nurse. She has been somewhat subject to these sweats at intervals for years but during the past few months they have been worse than heretofore. Changes in the ventilation of the bedroom, the amount of bed clothing used and so on seem to be entirely ineffective. Can you suggest anything in the way of treatment? Please omit name.

M D Kentucky

ANSWER—Hyperhydrosis is symptomatic of neurasthenia, anemia, obesity, general debility, or a combination of these. The patient may require as etiologic regimen, some form of rest cure or other change in her mode of living. She may need iron and arsenic, and/or a reducing diet if there is obesity. Roborant treatment, most especially in the form of tonic hygienic measures, is likely to be of advantage, and sea salt or alum may with advantage be added to the water. Strychnine in liberal doses and atropine in guarded dosage—so as not to produce distress—taken at bedtime may prove to be of temporary value until the more radical measures have had time to act.

KEYSTONE AND SNELLEN TESTS

To the Editor—In *Queries and Minor Notes* in *THE JOURNAL*, January 11 page 147, it was stated that a certain vision testing device 'does not exaggerate but rather minimizes the visual acuity as compared with that obtained by using the Snellen chart at 20 feet. Is this based on actual tests? Is there any published article to confirm that statement?

S H MONSON M D Cleveland

ANSWER—The observation that the Keystone test does not exaggerate the vision is made by a competent ophthalmologist using the test on school children. There is as yet no publication on the subject.

USELESSNESS OF PAINTING THROAT WITH MILD SILVER PREPARATIONS

To the Editor—Does painting the throat with mild protein silver or neosilvol do any real good in acute follicular tonsillitis? Please omit name.

M D New Jersey

ANSWER—No excepting to the extent to which relief is obtained by any cleansing of the tonsillar crypts stopped up with exudate.

Book Notices

California Medical Association Cancer Commission Committee Studies
Paper Price 75 cents Pp 129 San Francisco California California
Medical Association 1936

The California medical profession has been exceedingly active in the last few years in conducting effective educational campaigns among both the lay public and the profession. In 1931 the house of delegates of the California Medical Association created a cancer commission as one of the prominent commissions of the association. This small volume is the report for 1936. The presentation takes the form of a series of committee reports on various types of neoplasms made by groups of specialists. It is obvious from the technical form in which these papers are written that they are intended primarily for the medical profession. Different committees report on tumors from the various regions or organs and the Radiological Committee makes some general recommendations as to the use and limitations of radiation therapy. Contradictions that still exist on many of the questions discussed in this interesting and valuable pamphlet are frankly indicated. Owing to the limitation of space the discussion has obviously to be rather dogmatic but where there are differences of opinion attention is usually called to this fact. For example (on page 59) the Committee on Genito-Urinary Tumors states as regards kidney neoplasms that there is no value in preoperative treatment and recommends post-operative irradiation, but a footnote calls attention to the fact that there is a well marked division of opinion on the subject and that some believe that preoperative treatment only delays surgery. One member is quoted as saying "We have ample evidence of the value of preoperative radiation. It is not unusual to see an operable malignancy entirely done away with so that the operation itself becomes unnecessary." However, the committee adds that "it is hoped that in time sufficient statistical end-result evidence will be available to settle these questions." It is well to acknowledge that there are still many problems in the therapy of cancer which are still not solved and that any dogmatism on the subject is absurd.

This valuable little book should have a very wide circulation among the profession outside California as well as in it, and other state medical organizations might well learn a lesson from what has been done in California.

Le tonus cardio vasculaire et l'épreuve amphotrope sino carotidienne.
Par D. Danielopolu professeur de clinique médicale à la Faculté de
médecine de Bucarest. D'après les recherches faites en collaboration
avec MM. I. Marcou, A. Aslan, G. G. Proca et E. Manescu. Paper
Price 40 francs Pp 212 with 78 illustrations Paris Masson &
Cie 1935

This excellent monograph deals with a clinical study of the effects of pressure on the carotid sinus and of occlusion of the common carotid artery in a large series of normal persons and persons suffering from a variety of functional and organic cardiovascular diseases. After a brief outline of the history of the subject, the author discusses the mechanism of the nervous regulation of the heart and blood vessels in which field he himself has done some of the best pioneer work. He presents the view that there is both a humoral and a nervous control of the blood vessels and the heart. The nervous control is a dual one. In part it is mediated by afferent impulses from various parts of the body, acting primarily for the local control of the vessels, the stimuli are metabolic products, and the nerve pathway goes through the central nervous system. In part it is mediated by impulses from the carotid sinus and the root of the aorta, "the blood pressure regulators." The author develops this view in some detail and brings into line the hypothalamic and cortical control. The blood pressure regulators, he emphasizes, act both as pressors and as depressors. He discards as unfounded the simplification of the nervous control, which some workers have maintained exists. While the concept presented may not be accepted by all authorities in all its details, it has the distinct advantage of provoking further investigation.

In the next section the author describes in detail the manner of carrying out the tests of the excitability of the carotid sinus and of its tonic action. He has used the electrocardiogram and the Pachon-Vaquez method of recording blood pressure as measures of the effects. This is followed by a section deal-

ing with the responses obtained in various conditions. He points out that the carotid sinus reflex is normally tonically depressor in character. The response to stimulation in normal individuals may be pressor, depressor, biphasic or dissociated (i.e., pressor on some functions and depressor on others). An intense degree of stimulation is required in order to obtain a response. In pathologic conditions, the response obtained depends on the relative tone of the parasympathetic and sympathetic systems and on the presence or absence of myocardial lesions. Stimulation of the carotid sinus brings out latent abnormalities in cardiac function, therein lies its great prognostic and diagnostic value. While some of the facts presented are not in accord with concepts generally held, the method used and the analysis made are extremely valuable because they open up a new line of studying in man the correlative functions of the circulatory system in relation to its nervous regulation.

The section dealing with the author's theory of hypertension is particularly valuable. The author conceives of hypertension as being a specific involvement of the vascular system in which the local pressor mechanisms, presumably operating by way of afferent nerves, are overactive. The carotid sinus reflex in clinical hypertension, he finds, is decreased but, contrary to views previously expressed, is never absent. In fact, when there is organic heart involvement, it is actually hyperactive. He leaves the impression that the blood pressure regulators cannot combat the effects of the disturbance set up by the other nerve mechanism. The monograph must be referred to for other interesting details.

The illustrations present the electrocardiographic and blood pressure tracings on which the interpretations are based, together with several correlative diagrams. There are many case reports with tabulated summaries of data to illustrate the various points.

This monograph is highly recommended for the internist and the "cardiovascular" specialist as an excellent, stimulating summary of the author's views. The reader will be well repaid for the time spent in perusing it despite the fact that many of the views require further investigation for their confirmation.

My Life and Work. The Search for a Missing Glove. By Dr. Adolf Lorenz, Hofrath and Professor of Orthopaedic Surgery, University of Vienna. Cloth Price \$3.50 Pp 362 with 19 illustrations New York & London Charles Scribner's Sons 1936

This autobiography is a Horatio Alger type of story of a young Austrian peasant boy whose ambition and determination to become a gentleman were realized by his rise from poverty to fame and fortune. Fate and circumstances prevented him from doing aseptic surgery but he became a manipulator of bones and joints and popularized the art of what he called "bloodless surgery." His success, egotism, and a certain royal arrogance aroused the antagonism of his medical colleagues in Vienna. Obstacles of all kinds were thrown in his pathway but he refused to be discouraged. In his first visit to America he was received with enthusiasm by members of the medical profession and by the social and political leaders of the country. Few men have received the acclaim that was bestowed on him. The personality and superb showmanship of this "dry" surgeon delighted the imagination of the masses and made excellent newspaper copy. His name was in every newspaper and on the lips of most of the American people. Lorenz had become the famous gentleman of his childhood dreams. He had "found the other glove." During the war he dropped out of sight as far as this country was concerned. The large fortune which he had built up, much of which had come from wealthy patients in the United States, was lost. At the close of the war this man who had so loved the spotlight of world acclaim was "alt, krank und arm, dass Gott erbarm" (old, sick and poor, God have mercy). "To be old, sick and poor is the most terrible tragedy to befall a man." The headings of the chapters such as "Imported by America" and "Reconquering America" give a glimpse of his egocentric personality. The story of his trials when he returned to this country after the war to try to regain his wealth and position arouses a feeling of sympathy. He was ignored by the members of the medical profession, and few of his former admirers came to renew their friendship. A chapter entitled "Dimples and Indemnity Suits" relates with honesty and without apparent bitterness how he paid for some of his

errors of judgment or skill. Physicians and surgeons may read this book with mixed feelings of interest and distaste. The procedures which Lorenz called "bloodless surgery" are merely simple manipulations which are of value in a few types of conditions, but they are no longer surrounded by the veil of mystery which led a gullible public to believe them to be miracles. The lay reader may again be dazzled by the personality of Dr. Lorenz, and every one who loves the romance of success will find the book fascinating. Those who condemn the author for his love of the spotlight of public acclaim, his continual playing to the gallery or his mercenary attitude or who may be subconsciously jealous of him because of the financial success and world popularity which he achieved should be honest enough to admit after reading this book that some of the credit for the prominence of and interest in orthopedic surgery as a specialty belongs to Dr. Adolf Lorenz.

Differentialdiagnose in der Inneren Medizin. Von Prof. Dr. med. O. Naegeli, Direktor der medizinischen Universitätsklinik Zürich. Lieferung 1. Paper. Price 9.60 marks. Pp. 216 with 61 illustrations. Leipzig: Georg Thieme, 1936.

This is a highly condensed summary of the significant points in differential diagnosis. It is printed clearly on excellent paper and the illustrations, many of which are diagrammatic drawings, are ample and well chosen. The color plates, especially those depicting blood smears, are of the usual excellence associated with German printing. The book is the first volume of a three volume work (the second and third volumes to appear during 1936-1937) and includes discussion of the differential diagnosis of the anemias, hemorrhagic diatheses, leukemias, myeloid diseases, mediastinal and lymph node disorders, the common throat infections and diseases of the spleen, liver and gallbladder. It is presumed that the other fields of internal medicine will be considered in the succeeding volumes. Naegeli, a master of medicine, is unusually precise and brief. There is great stress placed on the chemical and morphologic changes of the blood and perhaps somewhat too little emphasis of the whole composite picture of the disease and especially of the important role assumed by the "history" of the patient. The trend toward overemphasis of laboratory data is more manifest in Germany than here. The immense value of laboratory diagnostic information is unquestioned and constant advances in technique and method of physiologic study of patients has added greatly to increasing accuracy in diagnosis, but clinical evaluation of such data must consider the patient as a whole and as the very core of diagnosis and treatment. In this work there is the suggestion of considering the patient as a loosely correlated collection of systems rather than as a finely integrated whole. Naegeli's discussion of the differential diagnosis of icterus, however, is particularly well done. The volume can be recommended as a concise and accurate consideration of the diagnostic problem in the field considered.

Anthrax Silicosis Among Hard Coal Miners. From the Office of Industrial Hygiene and Sanitation. Surg. R. R. Sayers, Medical Officer in Charge. Engineering Studies by J. J. Bloomfield, Sanitary Engineer and J. M. Della Valle, Assistant Sanitary Engineer. Medical Studies by R. R. Jones and Waldemar C. Dreessen. Statistical Analysis by Dean E. Brundage, Statistician and Rollo H. Britten, Senior Statistician. With Sections on Autopsy Material by J. W. Miller, Acting Assistant Surgeon and on Silica in the Urine and in Lung Specimens by F. H. Goldman, Associate Chemist. U. S. Public Health Service. Prepared by Direction of the Surgeon General. U. S. Treasury Department. Public Health Service. Public Health Bulletin No. 221. December 1935. Paper. Price, 25 cents. Pp. 114 with 75 illustrations. Washington, D. C.: Supt. of Doc. Government Printing Office, 1936.

Under an agreement with the mine operators the mine workers and the state of Pennsylvania the Public Health Service selected for detailed study a group of mines in the anthracite district. This bulletin gives a report of the investigation. The study of the dust exposure of the men included the nature of the dust, the size of the dust particles and the dust concentration in the different parts of the mines. The dust exposure correlated with each occupation resulted in an estimation of the exposure of the men 'per week, per month, or per year'.

Occupations which were dust producing and lead to severe exposures included 53 per cent of the men. Among men who did the drilling, especially the rock drillers the silica content of the material rose as high as 43 per cent of quartz. The greatest exposure underground was experienced by the regular

miners and rock drillers, while above ground the coal breakers and slate pickers experienced the highest exposure.

The physical condition of the men was determined by a routine examination including the occupational history, past medical history, history of present complaints or illness, and physical and roentgenologic examination. The group studied included 2,711 workers, of whom 361 with little or no dust exposure were considered as "normal." The remainder of the 2,711 men were examined in order to find those suffering from anthracosilicosis. A group of 135 disabled ex-miners were studied as a basis of "control."

In the 616 men found to be suffering from anthracosilicosis, special information was obtained. It was found that this group was subject to more attacks of pleurisy, pneumothorax and severe colds than the normals. They complained of more of the cardinal symptoms of the disease than the normal group. The physical manifestations of the disease were more prevalent and more pronounced in this group than among the normals.

Correlation of the physical appearances with the dust exposure disclosed that the incidence of anthracosilicosis was more pronounced in the dry mines than in those using wet drilling. Anthracosilicosis increased with increased dustiness, with higher quartz content of the rock worked and with longer years in the specific occupation and in the mining industry. A presumptive "threshold dosage" for the different exposures was suggested. When the quartz content was less than 5 per cent, the number of cases of anthracosilicosis was negligible if the dust counts were kept below 50 million particles per cubic foot of air. When the quartz content rose to about 13 per cent, the safe limit appeared to be from 10 to 15 million particles per cubic foot of air. In the case of those men exposed to quartz content as high as 35 per cent, the limit was set at from 5 to 10 million particles per cubic foot of air. These figures do not represent an unattainable level, as there were mines in which control measures had reduced the dust hazard below these figures.

The bulletin contains a section of reproductions of roentgenograms of the disease in different stages, which is a fine collection and a worthy adjunct to the report.

Terapéutica clínica. I. Agentes terapéuticos. II. Técnicas terapéuticas. III. Tratamiento de los síntomas. IV. Tratamiento de las enfermedades. Por el Dr. Alfredo Martinet. Con la colaboración de Desfossez et al. Tercera edición española corregida por el Prof. Dr. Lullier y traducida con notas y adiciones por el Dr. Angel Ortega y Díez. Prólogo del Dr. Teófilo Hernando, catedrático de la Facultad de medicina de Madrid. Paper. Pp. 1515 with 352 illustrations. Madrid: Casa Editorial Bailly Baillière, S. A., 1935.

In the third Spanish edition of this voluminous French manual of clinical therapeutics several supplements have been furnished by Ortega y Díez, the translator, and additional notes written by Lullier to adapt the book to the needs of Spanish practitioners; for instance, a list of spas and isothermic and isobaric zones in Spain, and rules regulating the dispensing of toxic substances in that country. Chapters on bacteriophage, vitamins, high frequency currents, asthma and insulin have been brought down to date. New additions discuss barbiturate poisoning, endocrine extracts, intravenous injections of alcohol in acute pulmonary processes, and pyretotherapy of dementia paralytica. The book is divided into four parts. The first, consisting of 481 pages, deals with therapeutic agents of various kinds: pharmaceutical, physical, dietetic, psychic. The second part describes the customary technical procedures such as cauterization, application of carbon dioxide snow, venesection, blood transfusion, gastric lavage and spinal puncture. The third part is devoted to symptomatic therapy. The causes of symptoms are arranged in alphabetical order. The author deplors this mode of treatment and realizes the fact that a scientifically minded physician bases his curative efforts on the recognition of etiology, pathogenesis and correct diagnosis of the underlying causes. It is questionable whether an extensive description of symptomatic methods of treatment does not enhance the condemnable practice of treating coughing, bleeding or pain without attempting to arrive at a diagnosis. The last part of the book describes the treatment of common diseases. It is evident that in view of such an arrangement of the work repetitions are unavoidable. The style is rather dry, no rhetorical

efforts have been made. The book contains a wealth of material and compares favorably with similar books in English. Being so voluminous, it may be considered rather as a reference book than a textbook on therapeutics.

Lectures on Diseases of Children. By Robert Hutchison M.D. LL.D. F.R.C.P. Consulting Physician to the London Hospital. Seventh edition. Cloth. Price £8 7s. 1p. 462, with 106 illustrations. Baltimore: William Wood & Company 1930.

In this edition the type has been reset and the chapter on chronic constipation in infancy and childhood and the chapter on infantile scurvy and pink disease have been rewritten. This volume of collected lectures is intended not so much as a textbook as a clinical approach to common pediatric conditions which, as the author states, are not usually dealt with in systematic lectures on medicine. The contents of the book are probably more suited to British readers than to students in this country, as the majority of subjects are well stressed in medical curriculums on this side of the Atlantic. It seems strange that neither under the discussion of the vitamins nor in the new chapter on scurvy does the author mention the discovery of the chemical nature of vitamin C. The treatment recommended for congenital syphilis is very conservative. The author favors mercury. He recommends neoarsphenamine with hesitation and he fails to mention sulfarsphenamine, bismuth or acetarsone. In his discussion on tuberculosis the student could hardly acquire the modern concept of the primary complex and the childhood type of this disease. The chapters on rheumatism and rheumatic carditis are well treated, and the chapters on the nervous diseases are comprehensive and well illustrated. The chapters on blood diseases and splenomegaly might have been brought more nearly down to date during the revision of this edition had such entities as Cooley's anemia and Niemann Pick's disease been included. The type is easily readable and the illustrations are excellent.

Insulin: Its Production, Purification and Physiological Action. By Douglas W. Hill B.Sc. Ph.D. Lecturer in Chemistry, University College, Exeter and Frederick O. Howitt M.Sc. Ph.D. F.I.C. Foreword by Professor E. C. Dodds. Cloth. Price 12s. 6d. Pp. 212 with 6 illustrations. London: Hutchinson & Co. Ltd. 1936.

A vast amount of literature is presented in this book in a systematized, condensed form and is thus made available to the many interested in the field of carbohydrate metabolism who are unable to follow the extensive literature as fully as they may desire. The subject is considered from both the chemical and the physiologic point of view. The historical background to the final isolation of insulin is well presented. The methods of preparation and purification of insulin are then described and finally various evidence bearing on the mode of action of insulin is discussed. The preface relates that the monograph is not intended to be used as a textbook but should be regarded more in the nature of a set of notes and that the authors purposely refrain from drawing what sometimes at least appear to be obvious conclusions. They merely collect and sift the evidence. That this has been a task of magnitude is indicated by the bibliography, which contains more than 1600 references. Author and subject indexes add to the value of the work as a book of reference.

Second Symposium on Silicosis. An Unofficial Transcript of the Second Silicosis Symposium Held in Connection with the Trudeau School of Tuberculosis at Saranac Lake, N. Y. June 3 to 7 1935. Edited by B. E. Kuehse, Claims Manager, Employers Mutuals, Wausau, Wis. Paper. Price \$3. Pp. 104. Wausau, Wis. 1935.

It is inevitable that these papers contain some repetition of the 1934 symposium material, as it is unlikely that the general subject of silicosis or even of its specialized divisions changes or develops greatly in the course of one year. The papers are valuable because they give in a rather informal way a review of opinions and facts as of June 1935.

R. R. Sayers presented the etiology of silicosis. D. E. Cummings talked on the estimation of dustiness, the taking of occupational histories, and the administrative control of silicosis. L. U. Gardner presented the pathology of silicosis. W. S. McCann gave the physiology of silicosis and discussed his procedure for estimating disability. A. R. Riddell and H. H. Kessler both talked on the clinical aspects of silicosis. D. M. Brumfield discussed the survey the Saranac Laboratories is conducting to determine the number of cases in sanatoriums and

the results of treating such patients. E. P. Pendergrass and H. L. Sampson both discussed the roentgen diagnosis of silicosis, presenting a large number of illustrations. Philip Drinker discussed the engineering control of silicosis, and the symposium closed with a discussion of silicosis as a social problem, by A. J. Lauza.

A considerable group of physicians and engineers attended both the 1934 and 1935 meetings, many of them coming both years. The meetings were all interesting and the discussions lively, in marked contrast to the conventionally dull affairs one encounters at most technical meetings. The papers are an annual report on silicosis and the meetings a forum at which to debate controversial matters. It is understood that the symposium cannot be held this summer but it is to be hoped that Dr. Gardner will arrange for another meeting in 1937.

The Early Diagnosis of Malignant Disease for the Use of General Practitioners. By Malcolm Donaldson F.R.C.S. M.B. B.Ch. Physician Accoucheur and Director of Cancer Dept. St. Bartholomew's Hospital. Stanford Code F.R.C.S. Surgeon to Out Patients Westminster Hospital. William Douglas Horner M.A. M.C. F.R.C.S. Consulting Surgeon. Thurot Dept. St. Bartholomew's Hospital. R. Ogler Ward M.Ch. F.R.C.S. Assistant Surgeon St. Peter's Hospital and Arthur Tudor Edwards M.A. M.D. M.Ch. Surgeon Westminster Hospital. Cloth. Price \$3. Pp. 168. New York & London: Oxford University Press 1936.

It has been said that the ultimate fate of the cancer patient lies in the hands of the first physician consulted, who in the great majority of cases is a general practitioner. The author in his introduction states that it is with the object of helping general practitioners to suspect, exclude and diagnose malignant or premalignant conditions that he and his colleagues have compiled this small book. There are twelve chapters, eight of which are written by Stanford Cade, one of the leading English authorities on the subject of cancer. The book is well written and covers the subject in a concise but thorough manner. With regard to biopsy Dr. Cade says "In my opinion the danger of biopsy is purely theoretical and entirely unsupported by practice." One of the best chapters in the book is on the early diagnosis of cancer of the breast. In this the author writes "early diagnosis of mammary cancer should be made with the mind's eye first, with the microscope next, and with the hands, eyes and nose last, if ever." This small book is unique and we know of no other that covers this subject. Contrary to the usual custom of textbooks it deals with signs and symptoms that are really early ones, rather than with the classic picture, which is usually one of advanced cancer. This book should be read by every practitioner of medicine and it is recommended as a textbook for senior medical students.

Monographien aus dem Gesamtgebiete der Physiologie der Pflanzen und der Tiere. Herausgegeben von M. Gildemeister, R. Goldschmidt, R. Kuhn, J. Parnas, W. Ruhland und K. Thomas. Band XXXIV. Physiologie des Menschen im Flugzeug. Von Dr. Gustav Schubert. Privatdozent an der Deutschen Universität Prag. Paper. Price 14.80 marks. Pp. 206 with 27 illustrations. Berlin: Julius Springer 1935.

This is the most complete treatise on the physiology of flying yet published. Each chapter deals with a separate system of the body wherein the stresses imposed and the tolerances found are fully discussed. A considerable portion of the work is devoted to a determination of the type and magnitude of the stresses developed during various aircraft gyrations, and this constitutes the greatest original contribution of the author. It is obvious from an examination of this book that much research remains to be done both to fill gaps in our knowledge and also to check a considerable amount of the previous work, which appears in many instances to be inaccurate or inconclusive. Each chapter contains several graphs and charts and is followed by a comprehensive bibliography.

The Early Diagnosis of the Acute Abdomen. By Zachary Cope, B.A. M.D. M.S. Surgeon to St. Mary's Hospital, Paddington. Seventh edition. Cloth. Price \$3 7s. Pp. 254 with 33 illustrations. New York & London: Oxford University Press 1935.

This monograph first appeared in 1921. The fact that a seventh edition has become necessary attests its popularity. The facts presented are familiar to every practitioner but seldom used in everyday practice. The author has added some new observations particularly with regard to the use of the x-rays. The work is of value to all surgeons who have fallen into a slight rut and reminds them of some of the things they learned long ago.

MEDICOLEGAL ABSTRACTS

Evidence Admissibility of Opinion of Expert Witness Based on Roentgenogram Not in Evidence—The courts of Missouri have hesitated, said the St. Louis court of appeals to hold that roentgenograms are not themselves the best evidence of what they show yet there is reason for such a holding. Differing from ordinary photographs, which in most instances can be fully understood and appreciated by the ordinary person who views them, roentgenograms in their very nature must necessarily be interpreted by an expert, else they are of no value to the jury. While a jury is entitled to have offered to it the best evidence of a fact which it is capable of passing on in the case of roentgenograms, so far as the jury is concerned the best evidence of what they disclose, at least from a practical standpoint, is the interpretation given them by the experts who examine them and who testify in as plain language as possible as to what their findings have been. In the present case, the deposition of an expert witness was admitted by the trial court setting forth the expert's interpretation of a roentgenogram. At the time the deposition was taken, the witness did not have the roentgenogram before him but based his testimony on a memorandum he had previously made. The admission of this testimony, said the St. Louis court of appeals, did not constitute error particularly in view of the fact that the witness stated that the roentgenogram was at his office and was made readily accessible for use by the defendant who objected to the admission of the testimony—*Arnold v Metropolitan Life Ins Co (Mo)* 89 S W (2d) 81

Malpractice Fragment of Needle Left in Chest After Thoracentesis—The defendant a physician, in treating the plaintiff for pleurisy with effusion, inserted an 18-gage hypodermic needle posteriorly between the seventh and eighth ribs. Owing to a sudden movement of the patient, the end of the needle broke off inside the thoracic cavity. A roentgenogram showed the fragment to be lodged in such a position that its removal was inadvisable, if not impossible. The patient recovered from the pleurisy, but the fragment of the needle caused him considerable pain and some disability. Eventually he sued the defendant. At the close of the plaintiff's evidence the trial court directed a verdict for the physician, and the plaintiff appealed to the Supreme Court of Minnesota.

The plaintiff contended that certain statements allegedly made by the physician immediately following the accident constituted an admission of malpractice, namely, that "he broke the needle" that he "should have used a stronger needle," that he "shouldn't have done it" and would "never try it again," and that the accident "couldn't be helped" because of "the handicap" under which he was working. The contention that the defendant himself admitted lack of the requisite skill to perform the operation, said the Supreme Court, lacks substantiating evidence. There was no evidence that he ever made any such admission expressly, and reasonable implication cannot make over into such an admission any words ascribed to him. It may be assumed, said the court that the jury could have concluded that the defendant himself believed that if he had used a stronger needle or had taken greater precautions to prevent the patient's moving during the operation the needle would not have broken. Regardless however, of whatever the defendant himself thought of the matter if in fact he conducted the operation according to the accepted standard of his profession, he cannot be held guilty of malpractice. Even assuming the truth of all the alleged admissions it does not follow that the defendant was guilty of malpractice. There was in the opinion of the court still no evidence from which the jury could have found reasonably that the defendant failed to perform the operation according to an accepted standard of his profession. The test is not whether the physician used his own best skill and ability. No one is always at his best. In the

absence of special agreement, one employing a physician has only a right to expect the ordinary skill and ability of his profession. If he lacks that, it is no defense that he did his best. If an individual physician possesses greater than the average skill, he is still not liable for malpractice so long as he uses the degree of skill and care of the average member of his profession. If the rule were otherwise, it would always be necessary to establish the particular physician's endowments of skill and ability, and there could be no fixed standard as to the ability which a patient would have a right to expect.

The Supreme Court concluded that even admitting the truth of the alleged admissions, a prima facie case for the plaintiff was not made out. The judgment refusing the plaintiff a new trial was affirmed—*Quickstad v Tavenner (Minn)* 264 N W 436

Medical Practice Acts Mandamus to Compel Issuance of License Refused—The state board of health of Missouri revoked the license of Dr. Lewis C. Schneider to practice medicine, on a charge of dealing illegally in narcotics. The medical practice act provides that any person whose license has been revoked shall have the right to have the proceedings reviewed, on a writ of certiorari, by the circuit court of the county in which the board held its meeting when the license was revoked. Dr. Schneider did not apply for a writ of certiorari, but, about two years after the license was revoked, he petitioned the circuit court for a writ of mandamus to compel the board to issue him a license. The circuit court gave judgment for Dr. Schneider and the board appealed to the Supreme Court of Missouri.

The board contended that Dr. Schneider had an adequate remedy by certiorari to review the board's action in revoking his license and that therefore mandamus would not lie. With this contention, the Supreme Court agreed. Mandamus, said the court, is an extraordinary remedy and will be granted only where there is no other legal remedy. Since the medical practice act expressly provides that the action of the board in revoking a license may be reviewed by certiorari, the writ of mandamus is not available. Accordingly, the Supreme Court reversed the judgment of the circuit court.—*State ex rel Schneider v Bourke (Mo)* 89 S W (2d) 31

Workmen's Compensation Act Compensability of Medical Disability Due to Silicosis—The employee, Borowski, had been exposed to silica dust for eight years. At the time of his discharge, July 31, 1932, he admittedly had silicosis. He later applied to the industrial commission for compensation. An award of compensation was affirmed by the circuit court, Dane County, Wis., and the employer and its insurer appealed to the Supreme Court of Wisconsin.

That the applicant sustained a medical disability during the course of his employment was conceded, but medical disability, said the Supreme Court, does not in the absence of an actual wage loss entitle an employee to compensation. No serious effort was made in the present case to show that the employee had actually sustained a wage loss resulting from his inability to perform his work because of silicosis. In the absence of any showing of wage loss, the employee was not entitled to compensation under the provisions of the workmen's compensation act. The judgment of the circuit court affirming the award, was therefore reversed—*Cham Belt Co v Industrial Commission (Wis)*, 264 N W 502

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

11:385-512 (April) 1936

Pulse Wave Velocity and Arterial Elasticity in Arterial Hypertension, Arteriosclerosis and Related Conditions. Florence W. Hynes, L. B. Ellis and Soma Weiss. Boston.—p. 385.

Relation of Arterial Pulse Pressure to Hemodynamics of Arterial Hypertension. Soma Weiss, Florence W. Hynes and Rose Shore. Boston.—p. 402.

Some Cases of Slow Pulse Associated with Electrocardiographic Changes in Cardiac Patients After Maximal Work on Krogh Ergometer. E. Biering, K. Larsen and E. Nielsen. Copenhagen, Denmark.—p. 416.

Aerocytoosis. Study of Circulatory Fault. A. H. Elliot, R. D. Evans and C. S. Stone. Santa Barbara, Calif.—p. 431.

*Double Aortic Arch with Total Persistence of Right and Isthmus Stenosis of Left Arch. New Clinical and X-Ray Picture. Report of Six Cases in Adults. A. Arkin. Chicago.—p. 444.

*Velocity of Blood Flow in Therapeutic Hyperpyrexia. I. Kopp. Boston.—p. 475.

Unusual T Wave in an Electrocardiogram. R. H. Halsey. New York.—p. 489.

Electrocardiographic Changes in Trichinosis. E. H. Cushing. Cleveland.—p. 494.

Double Aortic Arch—Arkin reports six cases of a clinically new aortic anomaly, two with postmortem observations. This consists of a total persistence of the right aortic arch, combined with a persistence of the left aortic arch in the form of the left subclavian artery, an isthmus stenosis and a diverticulum of the aortic arch (left descending dorsal aortic root), that is, a persistence of both aortic arches as in reptiles. The right arch lies behind the esophagus and the left arch in front of the trachea. The cases presented the following characteristic roentgen observations: 1. A shadow to the right of the sternum ran upward to the head of the right clavicle with a distinct systolic pulsation. 2. There was slight displacement of the trachea and definite displacement of the esophagus to the left. 3. The normal aortic knob on the left side was absent or there was only a small shadow of the descending arch on the left side, in some cases there were two aortic knobs, one on each side. 4. In the right oblique position the aortic knob was lying behind the trachea and esophagus, both of which were displaced forward and to the left (most characteristic of all was the circular forward displacement of the esophagus by the arch of the aorta). 5. There was a shadow of the diverticulum either in the retro esophageal knob or of the descending arch on the left side. 6. In the left oblique position a wide shadow of the ascending aorta was seen to the right of the trachea with evidence that the aortic arch ran behind the esophagus to reach the left side. The following clinical signs were found in the six cases: (1) dullness to the right of the sternum, (2) visible systolic pulsation in the second and third right intercostal spaces, (3) palpable, strong pulsation in the right supraclavicular fossa, (4) maximal intensity of the aortic sounds in the region of the head of the right clavicle, (5) slight displacement of the trachea to the left, (6) tracheal tug and (7) delay in the passage of the stomach tube at the level of the third dorsal vertebra, with transmitted pulsation from the arch of the aorta. Attention is called to the presence of aortic anomalies without any cardiac malformations and in many cases without clinical symptoms.

Velocity of Blood Flow in Therapeutic Hyperpyrexia—Kopp induced therapeutic fever in two patients with dementia paralytica, one apparently free from heart disease, the second with syphilitic aortic regurgitation and cardiac hypertrophy. The arm to tongue velocity time was determined by the decholin method. During the second half of the fever treatments of the

patient with an apparently normal heart an increase in the basal velocity of flow occurred and was accompanied by an increase in the pulse rate. The basal velocity of blood flow of the patient with syphilitic heart disease tended also to increase as fever therapy was continued but was accompanied by a slowing in the pulse rate. It is suggested that the changes in the basal velocity of blood flow and pulse rates of both patients are due to the beneficial effects of therapeutic fever on the myocardium, the changes in the patient with syphilitic heart disease resembling those characteristic of digitalis therapy. Therapeutic fever caused an increase in the velocity of the blood flow in both patients, but no absolute quantitative relationship was found between the percentage increases in the velocity of flow and the degree of temperature rise. The increases in the velocity of flow were least marked during typhoid vaccine fever. Based on average values for nearly similar rises in body temperature in diathermy fever, the increase in the velocity of the blood flow of the patient with syphilitic heart disease was much greater than that of the patient with an apparently normal heart. The response of the cardiovascular system to induced fever is proposed as a new test of cardiac function and reserve.

Hormone Studies with Ovipositor Lengthening Reaction of Japanese Bitterling—In their interpretation of some 1000 tests Kanter and his associates observed that the bitterling should be standardized if consistent results with the minimum of error are desired. In testing with commercial hormone products they found that estrogenic preparations gave uniformly positive results, the amount of hormone in rat units necessary to produce a positive test varying with the various products. The authors feel that in conjunction with one of the other biologic tests, the test on the bitterling will prove of value as an aid in diagnosis when ectopic pregnancy, incomplete abortion, missed abortion, placental polyp or any other condition in which the death of the fetus is suspected. Only when one is familiar with all the facts in any clinical problem can the test be applied as a diagnostic aid in pregnancy conditions. The authors' work shows that only those preparations containing estrogenic substance can influence ovipositor lengthening. Pregnancy urine from nonpregnant women at certain stages in the menstrual cycle, urine from sexually

active males, urine from women with cystic mastitis and extracts of some tumors give positive tests. The activating hormone is heat stable and apparently ether soluble.

Action of Estrogenic Substance in Menopause—Papanicolaou and Shorr describe the changes that take place in the vaginal secretion during the administration of estrogenic substance in two cases. With adequate amounts of the preparation there occurred a transformation of the vaginal smear from the menopausal to a type with large flat cells, largely cornified, with small pyknotic nuclei. This is the type of smear which is found normally during the follicular phase of the menstrual cycle just prior to ovulation. This change in the smear was generally associated with relief of the menopausal symptoms. With cessation of treatment or diminution of dosage, the smears gradually regressed and symptoms reappeared. A short period of bleeding usually followed, which is regarded as analogous to postovulatory bleeding. Biopsies of the vaginal wall at various stages during treatment showed a close correlation between the changes in the vaginal epithelium and in the vaginal fluid. As a result of treatment, the vaginal epithelium became hypertrophic with the more superficial cells showing cornification and small pyknotic nuclei. The outer basal zone was better differentiated and showed nuclear enlargement and mitoses. The daily dose required to induce complete changes in the smear and disappearance of symptoms varied from 250 to 3,000 rat units. Oral administration required a minimum of fifteen to twenty times the hypodermic dose. The vaginal smear test furnishes a simple objective guide for the treatment of the menopausal syndrome with estrogenic substance.

Treatment of Dementia Paralytica with Tryparsamide and Induced Fever—Solomon and Epstein treated nineteen cases of dementia paralytica and two cases of congenital neurosyphilis with tryparsamide and subsequent fever therapy. These

twenty-one patients were chosen for fever treatment from a series of eighty-one cases treated with tryparsamide because their response was not satisfactory. The results obtained after fever were good, both clinically and serologically, in every case. In almost every instance the cerebrospinal fluid became negative, and in the majority of cases the spinal fluid response following malaria was much quicker than is to be expected in cases treated from the outset with fever. The authors conclude that a considerable number of preliminary injections of tryparsamide greatly enhance the probabilities of therapeutic success in the treatment of dementia paralytica with fever, and the improvement of the spinal fluid observations occurs more rapidly following fever if the patient has first been prepared by treatment with tryparsamide.

Method for Staining Nerve Fibers—Bodian found that paraffin sections could be impregnated with strong protein silver and the silver reduced with hydroquinone, to give selective and sharp staining of nervous elements, only provided that a small amount of metallic copper or mercury was added to the silver bath. This method has been found invariably successful in demonstrating, in properly fixed material, myelinated fibers and the finest unmyelinated fibers of central and peripheral nervous systems, the end feet of Held, neurofibrillae and other nervous elements. It can be used successfully on brain, spinal cord, peripheral nerve, old formaldehyde-fixed human material and sections stained previously with toluidine blue. Briefly the method is as follows: 1. For serial paraffin sections of whole brains, fixation by perfusion with 80 per cent alcohol is most satisfactory. 2. The paraffin may be removed with xylene and sections run through absolute alcohol and 95 per cent alcohol to distilled water. 3. The sections may be placed in a solution of 1 per cent strong protein silver containing from 4 to 6 Gm. of metallic copper per hundred cubic centimeters of solution, for from twelve to forty-eight hours at 37 C., and are washed in distilled water. The silver can be used only once. 4. The section is placed in a reducing solution of 1 Gm. of hydroquinone, 5 Gm. of sodium sulfite and 100 cc. of distilled water for ten minutes and then washed thoroughly in distilled water. 5. Gold is toned in by placing the section for five minutes in a solution of 1 per cent gold chloride containing 3 drops of glacial acetic acid per hundred cubic centimeters of solution, and washing it in distilled water. If sections do not have a light purple color they are placed in a 2 per cent solution of oxalic acid until the entire section has a definite purplish tinge and then washed in distilled water. The residual silver salts are removed with a solution of 5 per cent sodium thiosulfate in from five to ten minutes. 6. The sections are washed thoroughly in distilled water, dehydrated and mounted in balsam. The author used the method to stain, simultaneously by means of a rack, about 600 paraffin sections of the opossum brain with uniformly brilliant impregnation throughout and no objectionable precipitate on either sections or slides.

Surgical Treatment of Epileptiform Seizures—Davis and Droegemuehl studied all their patients having intracranial tumors in an effort to determine whether the attacks were more frequent after operation remained the same were less frequent or did not recur. Of the patients with glioblastomas, 10 per cent of those having attacks prior to operation had none after operation up until the time of death and 32 per cent had fewer and less severe attacks following operation. Of the astrocytoma group, 31 per cent were judged to be unimproved as far as their convulsions were concerned. 50 per cent had fewer and less severe attacks and two (6 per cent) had no attacks following operation over an interval of three and six years, respectively. These figures approximately represent the condition that exists in the other tumors in the glioma group. Of the meningioma group three patients were definitely worse following operation and finally had to be placed on bromide or phenobarbital therapy. Eight patients had fewer attacks which were less severe but were not entirely free in spite of the fact that their tumors had been removed completely. The remaining five patients who had convulsions before operation had no further convulsions following removal of their tumor and have been without bromide or phenobarbital therapy. It becomes apparent that although these tumors have been removed completely, certain changes must have been produced within the brain which continue to act as irritative foci releasing a convulsive discharge. These changes may be and probably are microscopic in nature, and further surgical procedures under such circumstances are illogical and contraindicated. Particularly is this true when these attacks can be so well controlled by judicious medicinal therapy. In general the removal of an intracranial tumor is followed in the majority of patients by definite improvement in the frequency and severity of the convulsive seizures. It cannot be guaranteed however, that the attacks will completely disappear. It is now the authors' custom to begin bromide or phenobarbital therapy preoperatively on those patients who give a history of convulsive attacks and to continue that therapy after operation. By maintaining a constant bromine level in the blood the patient's attacks can be stopped and the dosage of bromides reduced gradually.

Ulcer of Pyloric Sphincter—In eleven years Horsley operated on twelve patients with peptic ulcer either solely (nine) or partly within the pyloric ring. A partial gastrectomy, a modification of the first method of Billroth was done

That partial gastrectomy is the proper treatment for this type of ulcer seems to be supported by a consideration of the clinical and pathologic features of the lesion. A true ulcer of the pyloric sphincter always has a background of pyloric (gastric) mucosa, because this mucosa normally lines the pyloric sphincter. An ulcer of the pyloric ring, then, is a gastric ulcer the symptoms of which are usually accentuated. The average age of these patients was 46.6 years. Two of them were women and ten were men. The average duration of symptoms was ten and three-fourths years, the duration of the symptoms varying from three months to twenty years. Several of the patients gave a long standing history of indigestion, but the severe symptoms were of only recent date. There was severe pain in nine cases, mild pain in one case, and two patients complained of no actual pain. In the latter two cases there was vomiting of much blood, and there was some bleeding in one other case. In nine cases there was a history of vomiting. A gastric analysis was done in ten of these cases. The average value for free hydrochloric acid was 32.9 units. The highest average value of free hydrochloric acid in any one case was 75. In two cases there was no free hydrochloric acid. In ten cases a roentgenologic examination was made, and in three obstruction was present after twenty-four hours.

Shoulder and Clavicular Pain in Appendicitis—In 1923, Mastin's attention was called to a case of appendicitis in which pain was referred to the region of the shoulder and clavicle. The second case was seen eleven years later. Recently he sent out 485 questionnaires relative to this subject. In the 351 answers received, three instances were reported. A complete review of American and foreign literature from 1920 to 1935 revealed six additional cases, bringing the total to eleven. Relief of the pain in the upper chest and shoulder region in his two cases following appendectomy indicates that the pain was caused by inflammation of the appendix, consequently it was referred pain. Since the area to which the pain was referred is supplied by the third, fourth and fifth cervical nerves, the afferent impulses arising at the site of the inflammation must have entered the spinal cord in the corresponding cervical segments. The only nerve connected with this segment of the spinal cord, which includes afferent fibers that reach the abdomen, is the phrenic. Consequently these must be regarded as cases in which the pain was referred by way of the phrenic nerve. A possible explanation of this symptom complex is offered by an anatomic diagram showing a communication between the phrenic nerve and the terminal branches of the superior mesenteric plexus. Distribution of phrenic fibers to the appendix must be regarded as anomalous, otherwise this symptom complex would occur more frequently.

The Sympathetic Nervous System in Migraine—Solomon discusses the need for an accurate means of continuously measuring the activity of the sympathetic nervous system in the study of migraine. The method of utilizing the electrical resistance of the skin is presented for the purpose. In seven patients with migraine the electrical resistance of the skin was measured continuously during the period of relief from a characteristic headache obtained by the use of ergotamine. There was no significant change in any instance, indicating

that the relief from the headache was not accompanied by a change in the activity of the sympathetic nervous system as a whole. In one case a similar lack of change was observed during the spontaneous disappearance and reappearance of the headache. In another, a "march" of neurologic symptoms during a typical headache was likewise unaccompanied by any change in the electrical resistance of the skin. In four control patients without headache, ergotamine caused no change in the electrical resistance of the skin.

Calvarial Hyperostosis and the Accompanying Symptom Complex—Moore states that reexamination of the roentgenograms of 6,650 human skulls disclosed four types of thickening of the calvaria: internal frontal hyperostosis, frontal nebula, diffuse calvarial hyperostosis and frontoparietal hyperostosis. The type of thickening which is most characteristic and which led to the study involves the frontal bone, which has on its inner table deposits of new bone with occasional extensions to other bones in the base of the skull. This overgrowth or deposit of cancellous bone lies on the inner table and is covered on its intracranial aspect by a smooth lamella of compact bone. This deposit of bone is increased in density, as seen in roentgenograms. Increase of density progresses from the inner table outwardly through the diploe. The hyperostotic deposit is progressive, and roentgenographically it can be divided into degrees of development. Morphologically, it may be either nodular or sessile. In all the hyperostoses there is bilateral symmetry, both in extent and in degree, of the osseous changes. There is no change in the outer table of the skull, which remains regular and smooth. The skull does not increase in size, so that the increased volume of the bone has to be accommodated at the expense of the capacity of the cranial cavity. The incidence of all types was 35 per cent. The fact that the hyperostoses coexist in the same persons and that the skulls are generally thickened in cases of all types sustains the view that, though morphologically distinct, all types have the same fundamental etiology. The symptoms described in the case histories are a combination, more or less constant, of headache (often disabling and in patients with internal frontal hyperostosis frequently referred to the forehead with occasional tenderness and a feeling of pressure), obesity, muscular weakness, easy fatigue, "nervousness," depression, dimness of vision and occasional diplopia, epileptiform seizures, mental slowness, dizziness, and disturbance of equilibrium and gait. The symptom complex and the roentgen evidence are so characteristic that, when the one is observed, the appearance of the other may be foretold in a substantial proportion of the cases. Probably the symptoms antedate the osseous changes. The differential diagnosis of the disorder has to be made first from osseous dystrophies. The unequal incidence in the two sexes (98 per cent in women) separates these conditions from other osseous dystrophies, practically all of which occur with approximately the same frequency in the two sexes. The condition is one of rather late adult life. The evidence is that the condition is a metabolic disease in which, as far as is known at present, only fat and calcium metabolism is at fault. The patients sooner or later come under the observation of the neurologist or neurologic surgeon. Unquestionably the psychic manifestations, if progressive, terminate in dementia. In cases of internal frontal hyperostosis it appears that much good might be accomplished by turning down a frontal bone flap. Failure of vision might be helped by decompression of the optic nerves. It is useless to administer antisyphilitic treatment in the belief that the disorder is cerebrospinal syphilis. The administration of thyroid on the theory that thyroid insufficiency is a part of the disease seems out of place in these cases unless hypothyroidism is a known complication of the disorder.

Neuropsychiatric Syndromes Associated with Frontal Internal Hyperostosis—Carr has observed seventeen cases of hyperostosis of the internal tables of the frontal bones. The observations concur with Moore's opinion that there is a symptom complex or syndrome associated with these changes in the bones of the skull. The importance of the recognition of hyperostosis of the frontal bones of the skull lies in the fact that it assists in more accurately classifying cases of this condition, in many of which the changes in the frontal bones have masqueraded as tumor of the brain or as reactions asso-

ciated with chronic invalidism. The changes in the frontal bones of the skull could not possibly account for the composite picture or the pictures presented by individual patients. These changes must be considered purely roentgenologic evidence of an entity that is probably metabolic in origin. Menstrual disturbances of various kinds occurred in thirteen of the seven teen patients. There has been some fluctuation in symptomatology, but headache, weakness, dizziness and defective memory were consistent complaints. The psychiatric changes varied widely but were predominantly a confusional state of greater or less duration with marked irritability and memory defects. An attempt has been made to treat a group of these patients with aminoacetic acid by feeding large quantities of gelatin daily. Aminoacetic acid therapy was originally used in an attempt to relieve the marked weakness complained of by one of the patients. The change in the entire picture was so striking that its use has been continued. Several patients have been studied from the point of view of creatine-creatinine metabolism. These patients showed creatinuria, which disappeared under therapy with aminoacetic acid.

Experimental Studies on Headache—Clark and his colleagues suggest that the headache following the injection of histamine is the result of a discrepancy between the behavior of the blood vessels inside the head as compared with those elsewhere. The rise of the systemic blood pressure after its fall indicates that at least a portion of the total vascular bed is constricting. However, the cerebral vessels remain dilated for a short time, and the cerebral blood flow is increased. In fact, with the rise in systemic blood pressure the cerebral arteries are still further dilated and bear the brunt of heightened intramural pressure with each cardiac systole. Moreover, the ability of the now hypotonic walls of the vessels to absorb pressure changes is much reduced and the pressure variations within the vessels are thus more directly transmitted to sensory end-organs in and about their walls and to the subarachnoid space. It is suggested that the combination of these two factors causes headache through the stretching effects on the walls and perivascular tissues of the larger dural and pial vessels, chiefly the arteries. The walls of these vessels are the sites of origin of the afferent impulses interpreted as pain.

Neoparsphenamine in Treatment of Nonsyphilitic Inflammations of Uveal Tract—Having obtained gratifying results in an apparently hopeless case of sympathetic ophthalmia with the use of neoparsphenamine, Lucic considered it worth while to try this drug in the treatment of other types of nonsyphilitic uveitis. He found neoparsphenamine of definite value in the treatment of acute and chronic iridocyclitis of doubtful etiology and of that due to focal infection. Neoparsphenamine is administered by the intravenous route and the individual dosage is that recommended by syphilologists for the patient with syphilis. It is rarely necessary to give more than four injections in the treatment of acute iritis. In the treatment of chronic uveitis and of sympathetic ophthalmia it is essential to administer several intermittent injections. In each case one is guided by the reaction caused and the clinical results obtained. It is well to remember that in a majority of the cases the drug is being administered in the presence of a focus of infection and that complications may arise. Whenever possible the administration of arsphenamines should be undertaken only by one versed in this specialty.

Effects of Roentgen Therapy on Gliomas—Deery studied a group of fifty gliomas to determine the effect of irradiation. Only cases were chosen in which both preradiation and postradiation specimens of the tumors were available. The preradiation specimen was obtained when the tumor was first attacked surgically and the postradiation specimen from a second operation or at necropsy. The types comprising the bulk of the series were medulloblastomas, glioblastomas and astrocytomas. Some of the tumors of each type showed striking histopathologic changes which it seemed reasonable to credit to the radiation received. The histopathologic changes considered to be due to irradiation seemed primarily to affect the tumor cells themselves. Manifestations of cell injury were found often which, when severe, resulted in death of the cell. There was an increase of necrosis and often an appreciable reduction in cellularity of the growth as determined by actual cell counts. Mitotic figures in general were less frequent following irradiation. Postradiation specimens sometimes showed the appearance of or increase in giant cell forms. It is the author's impression that the blood vessel and connective tissue phenomena commonly seen in postradiation material are secondary and essentially incidental changes. Histopathologic changes, apparently caused by roentgen therapy were encountered not only in tumors of a lower order of differentiation such as the medulloblastoma, but also in tumors of a high degree of maturity, such as astrocytomas. Exact information on the reactions of gliomas to irradiation must await the acceptance and adoption of clearly defined standardizations of certain factors which directly affect the statistics of the problem. Chief among such factors are a more exact description of the location and size of the tumor, more exact statements as to the operative procedure carried out on the tumor itself, standardization of the pathologist's evaluations of the degree of malignancy of a given tumor, and finally a general acceptance of what constitutes adequate radiation dosage as well as comparable roentgen therapy technic.

Changes in Blood Esterase in Multiple Sclerosis—Brickner and his associates examined serum esterase of eighty-nine cases of multiple sclerosis and 617 controls (100 medical students and 517 patients suffering from conditions other than multiple sclerosis). Until now it has been necessary to refer to the blood factors investigated as 'lipolytic agents' or even 'lipolytic conditions'. It has not been definitely shown whether they were of enzymic character or not. The lipolytic factor of the present investigation satisfies the thermolability requirements for enzymes. The tests have been made by measuring the degree to which serum can cause the breakdown of an ester (methyl butyrate) into fatty acids. For these reasons the active

agent in the blood is referred to as an esterase. The esterase values are not distinctive for multiple sclerosis as such, but in the scale of values determined for a large number of cases of all kinds it was found that, during the active stage of multiple sclerosis, the spontaneous values are low and, in the inactive, high. Probably although final statement cannot be made at present, the values are highest at the beginning of inactivity.

Primary Aplastic Anemia—Recovery—Astwood's case with complete recovery presented the characteristics of primary aplastic anemia. Whether or not this recovery will be permanent only time can tell. To what extent the different remedies used (citrate blood, liver extract, ferric ammonium citrate, brewers' yeast, raw bone marrow, epinephrine, ephedrine) influenced the outcome it is difficult to say, but the author is certain that the patient would have died promptly but for the transfusions, of which there were eight, of about 400 cc. average, given at weekly intervals. The rise in reticulocytes and the gradual improvement which followed the use of ephedrine suggest that it may have exerted some beneficial action on blood regeneration. It is probable, however, that the recovery was spontaneous and that the absence of any heroic measures, the supportive effect of the transfusions and the prevention of infection by good nursing allowed recovery to take place. The concept of complete bone marrow aplasia as necessary to the diagnosis of aplastic anemia is probably false. As spontaneous recovery may occur in some cases, prolonged supportive treatment with repeated blood transfusions is justified.

Ragweed Dermatitis—Caulfield believes that the profession in general does not appreciate that definite types of dermatitis may follow the inhalation of substances normally in the air. The results of his investigation of a case of "tulip fingers" have shown the ether-soluble portion of the tulip bulb to be the cause of the dermatitis. The intramuscular injection of this fraction taken up in corn oil prevented the outbreak of a severe dermatitis for the first time in a seasonal exposure of a duration of five years. This ether-soluble fraction in oil gave a less pronounced patch test with another individual who experienced mild symptoms on his seasonal exposure to tulip bulbs. A case of ragweed dermatitis is added to the list of cases already reported. The exciting factor was found to reside in the ether-soluble portion. The attacks occurred for a period of ten years during the early growth of the weed and before the pollen content of the air had appeared in any considerable quantities. During the height of the pollen air content the dermatitis had subsided without the advent of any symptoms of an allergic character. A case of urticaria-like skin and mucous membrane eruption, of a strictly seasonal character, was found to give positive scratch tests to different pollens, but more particularly to ragweed pollen that corresponded to the seasonal air content of the pollens giving positive tests. A positive Prausnitz-Kustner reaction was obtained with a solution of ragweed pollen whereas patch tests with all fractions of ragweed pollen were negative. A table based on the scratch

and patch tests and the Prausnitz-Kustner reaction attempts to give in graphic fashion the fundamental differences between cases of contact dermatitis and the prevalent conception of allergic or atopic dermatitis

Experimental Whooping Cough in Chimpanzees—Rich and his co-workers produced a condition similar in all respects to whooping cough characterized by convulsion followed by a protracted, paroxysmal cough typical of that of pertussis, associated with lymphocytosis and the development of positive complement fixation toward the Bordet-Gengou bacillus, in the chimpanzee by the oral inoculation of unfiltered tracheal exudate from human pertussis. Bordet-Gengou bacilli were recovered on cough plates at the height of the cough. A precisely similar condition has been produced in the chimpanzee by oral inoculation with pure cultures of Bordet-Gengou bacilli. The inoculation of apes with bacteriologically sterile blood and filtered respiratory secretions obtained from each of four cases of pertussis early in the disease was followed by the appearance of a catarrh of the upper respiratory tract without cough. In the one instance in which an attempt was made to transfer the agent from one ape to another by means of a bacteriologically sterile filtrate of the nasopharyngeal secretions the attempt was successful. The nature of this filtrable agent is discussed, but the authors limited data do not permit them to conclude that it is a specific filtrable virus that acts to increase susceptibility to infection with the Bordet Gengou bacillus analogous to the action of the filtrable virus of swine influenza or canine distemper. Its relation to pertussis is undetermined. At present one can say only that the Bordet-Gengou bacillus acting alone, is capable of producing the characteristic clinical manifestations of whooping cough in the ape.

Quinine Amblyopia—Simpson reports a case of quinine amblyopia. The patient's normal sense of light has not returned in almost five years and she has difficulty in getting around at night. The diagnosis of the condition depends on the history of quinine ingestion and the following five points set forth by Ball: 1 Vision is lost completely, almost suddenly. 2. There are attenuated retinal vessels and white papillae, and often there is a remarkable recovery of function. 3 Central vision returns first, while peripheral vision is restored slowly and seldom if ever completely. 4 The color sense is often damaged, if it returns at all, it does so first at the center and then extends peripherally. 5 Diminution of the light sense, with resultant night blindness, is a frequent sequence of quinine poisoning. Though the prognosis is favorable to the restoration of good central vision, no doubt in certain cases good central vision is not regained. In the prevention of this disease, when a large amount of the drug or a long continued dosage of a smaller amount is contemplated, the history of an idiosyncrasy is a warning, which may be elicited by Baer's skin test as recommended by Rucker using a 10 per cent solution of quinine bisulfate.

Acetylsalicylic Acid as a Factor in Heart Disease—Temple believes that the general increase or excessive use of drugs is at least in part responsible for the increase in fatal heart disease. It has become a common practice among many people to make free and unlimited use of acetylsalicylic acid as a cure-all for every ache or pain to which human flesh is heir. The drug is classified in the general group of coal tar derivatives, among which are acetanilid, antipyrine, acetophenetidin and other well known heart depressants. The physiologic action of any of this general group or class of drugs is to reduce arterial tension and weaken the contractility or elasticity of the muscular fibers of the heart. By the excessive and continuous use of acetylsalicylic acid the heart muscles become soft and flabby, the heart valves relax and lose their power to perform their normal function properly and, by degrees, the blood begins to regurgitate with each heart pulsation back into the blood vessels thus gradually resulting in a valvular heart lesion which, when once established, is never cured but continues to grow worse and worse until death results. Acetylsalicylic acid is potentially a dangerous drug and its use as a

home remedy is a menace to the good health of the people. Its indiscriminate use, as urged in advertisements of all types as a harmless and innocent drug is inimical to public health and should be discouraged. The question is to what extent the excessive use of acetylsalicylic acid has influenced the rapid increase of fatal heart disease among the people since 1900 should command the attention of health authorities.

Surgical Treatment of Diaphragmatic Hernia—Harrington believes that operative replacement of the herniated viscera in the abdomen, with repair of the abnormal opening in the diaphragm, is the only treatment that ensures complete relief of symptoms. The hernial opening is best repaired through an abdominal approach, with the use of fascia lata and interrupted linen sutures. Temporary or permanent interruption of the phrenic nerve is of value as a procedure preliminary to radical closure of large openings, particularly when there is deficiency or loss of structure of the diaphragm. Radical repair of the hernia was carried out in ninety-seven cases. There were ninety-eight patients who recovered from operation. Of the eight treated palliatively by interruption of the phrenic nerve one has since died of angina pectoris, two died of causes not definitely ascertained, but which apparently were attributable to cardiac conditions, for they had had myocardial degeneration at the time of the operations, and the remaining five have obtained partial relief of symptoms. Ninety patients recovered from radical operative repair of the hernia; eighty-eight patients have been completely relieved of symptoms and two have had a return of symptoms following recurrence of the hernia. In one of the cases, recurrence developed following an influenzal type of pneumonia three months after operation; the recurrence being caused by the severe strain of coughing. In the other case there is no known cause for the recurrence. All patients have been examined roentgenologically every six months to a year after operation. There are no serious physiologic effects from repair of these defects in the diaphragm. The diaphragm which has been operated on functions normally after repair unless the phrenic nerve or some of its branches have been destroyed, paralyzing that portion of the diaphragm supplied by them.

Prevention of Peritonitis After Operation on Biliary Tract—Coughlin points out that in the prevention of peritonitis the falciform ligament becomes a structure of great value for the prevention of adhesions between the raw surface of the liver and the adjacent stomach and duodenum if it is properly utilized, its free edge sewed to the peritoneum covering the common duct, then skirting the duodenum and catching the gastrocolic omentum below. If with the drain reaching from the foramen of Winslow to the surface by the shortest route, which is out through the upper end of the wound, the patient is turned on the left side, all secretions from the region of the site of operation will flow down hill. They cannot spread to the left because of the falciform ligament and the use that has been made of it, and they will not accumulate round the site of operation and spread, carrying virulent bacteria perhaps to all quarters of the peritoneal cavity. In twenty-four hours the area will have become "walled off." For drainage after operations on the biliary tract the patient is turned on the left side. The abdomen is turned slightly toward the bed and this position is maintained at least for the first twelve hours and by preference for twenty-four. The author has been using this method since 1912. He has records of 287 cases that required drainage, with only one patient who died of peritonitis and this patient would not remain in a position to favor drainage.

Hemorrhagic Telangiectasia of the Osler Type—Telangiectatic Dysplasia. Isolated Case with Discussion on Multiple Pulsating Stellate Telangiectases and Other Striking Hemangiectatic Conditions F P Weber—p 182

Streptococcal Dermatitis—Kinnear asserts that until recently the streptococci causing impetigo and streptococcal dermatitis have not been differentiated, and in view of the marked differences between the clinical appearances of these diseases this has led many to reject the streptococcal origin of the latter. The active stage of streptococcal dermatitis is characteristic. The red, glazed area with its abundant exudation of serum from the whole surface is quite easily distinguished from both eczema and other forms of dermatitis. The less active phase of the disease, streptococcal pityriasis, is also characteristic. The scaling is a fine lamellar exfoliation and may be profuse. Occasionally this stage of pityriasis is the primary stage of the disease without a preceding dermatitis, frequently when the scalp is acutely involved, patches of dry pityriasis are found on the body, but it is most commonly found as the active stage is passing and is almost invariably at the margins of an acute lesion, especially in the scalp above an intertrigo behind the ear. All gradations between these two phases may be found, frequently in the same patient in different parts of the lesion. Streptococcal dermatitis attacks the folds of the skin and spreads from the folds to the neighboring skin and, as the disease is brought under control, it gradually contracts till again the folds alone are affected. Impetigo has not the same tendency to affect the folds. The lesions of impetigo are comparatively small and, when a large area is affected, one can see that it is by numerous distinct elements. On the other hand, the continuity of the lesion in streptococcal dermatitis is evident. Vesicle formation such as occurs in impetigo is absent in streptococcal dermatitis. As a rule it is not difficult to distinguish streptococcal from other forms of intertrigo. The extent of this streptococcal infection may vary from a tiny lesion at the upper end of the retro-auricular fold to a generalized involvement of the whole surface of the body. It may disappear spontaneously in a few days or last for years. For treatment during the acute stage a nonirritating antiseptic in solution is best. In the less active stage coal tar is invaluable. The causal organisms of impetigo and of streptococcal dermatitis are entirely different types of streptococci. The author found that one could isolate from impetigo a hemolytic streptococcus, whereas from streptococcal dermatitis an anhemolytic streptococcus was obtained. In cases of a mixed type both streptococci were found.

When Should Refills Be Stopped?—Dundee believes that the extent and nature of the original lesion is the most important factor in the decision as to when treatment should be

stopped. The smaller the original lesion, the more confidence can one have regarding expansion. Patients who continue to have intermittent positive sputums ought to have their treatment continued indefinitely. A complete roentgen serial of each case should be in the hands of the current operator. When the patient leaves a sanatorium or changes doctors, all his roentgenograms should be transferred with him. The most important change to look for roentgenographically in lung reexpansion is a reappearance of excavation, for such an occurrence warrants an immediate reversal of treatment, with closure of the cavity. Lesions that have undergone little resolution during treatment, contain little or no calcium and have made little or no attempt at stellar formation or fibrosis, and yet have no perifocal exudate, should be considered carefully before reexpansion is resorted to. Such innocent-looking lesions, if large, undoubtedly contain tubercle bacilli. If these lesions have not healed under pneumothorax, they certainly will not do so after reexpansion, and they may go on to central caseation, followed by liquefaction and excavation, if collapse is not maintained. The development of a serous effusion toward the end of artificial pneumothorax treatment should be prevented from interfering with the desired degree of collapse by performing frequent aspirations and necessary air replacements. The younger the patient, the more inclined is the author to prolong pneumothorax treatment. Relapses following reexpansion are more common during the years from 15 to 30 than later. The patients who have to return to hard manual labor should have pneumothorax treatment continued considerably longer than other patients, and a larger proportion of this group than of any other should have pneumothorax continued indefinitely. The more contacts there are to any particular pneumothorax case, the more careful one has to be about terminating the treatment. A considerable number of relapses occur in women after reexpansion probably because of pregnancy and the care of the child. When there has been a great deal of original lung destruction, pregnancy is not advisable. When the involvement has been less and the economic and home conditions are satisfactory, pregnancy may be considered safe, provided pneumothorax is continued for at least one year after full term. This applies to patients in whom pneumothorax has been satisfactory and who have had a negative sputum for three years.

Latent Adolescent Pulmonary Tuberculosis—Wingfield and Macpherson observed that in taking histories of recently diagnosed adult cases there is often a suggestion of a definite period of ill health in adolescence which might be ascribed to active pulmonary tuberculosis but which had not been recognized as such. As examples they mention pleurisy, atypical pneumonia or bronchitis, anemia and nervous breakdown for no known cause. Perhaps the extensive lesions of adult disease are really in many cases deposited during adolescence with the accompaniment of slight or unexplained constitutional disturbance that these lesions are carried unrecognized, perhaps extending slowly and without symptoms until they make their presence known in adult life either by reason of their spread past a definite point or because some environmental cause has allowed of their reactivation. If this hypothesis were true, the roentgen examination of a sufficiently large unselected sample of the adolescent working-class population in normal health should reveal a proportion of cases with definite lesions. Further, the incidence of these lesion carriers should closely approximate the incidence of clinically manifest tuberculosis in the adult working-class population between the ages of 21 and 40. Scholars in all the county secondary schools were approached and in this way 1,350 cases of both sexes between the ages of 14 and 18 years were examined. Employers of adolescent labor were interviewed and 1,031 more cases were

obtained of the adolescent, urban and semiurban working-class population between the ages of 14 and 21. These adolescents were, so far as the authors knew, in normal health. The authors considered positive those roentgenograms in which there were unmistakably abnormal shadows, indicating definite pathologic changes in the lung parenchyma, having the appearance that was compatible with, and usually associated with, tuberculous lesions of the adult type. In the 2,381 roentgenograms there were fifteen (0.65 per cent) positives. In addition there were eighteen abnormal roentgenograms, and ten of these showed shadows probably due to tuberculous lesions. Therefore a definite incidence of 0.65 per cent was found and a possible incidence of 1.08 per cent. Similar investigations undertaken by workers in other countries revealed a much higher incidence of latent lesions. Such lesions are always liable to spread and to intensify, even though they remain stationary and symptomless for long periods. A proportion of these adolescents with their latent lesions will sooner or later exhibit clinical disease. The incidence of these latent lesions among adolescents approximates closely the estimated incidence of clinical disease among adults. If these adolescent carriers can be detected it is comparatively easy to handle them so that they will never develop clinical disease or so that the development in them of clinical disease will be postponed until much later in life—every year of postponement making such development less likely.

Experiments with Protamine Insulinate—On the basis of their studies, Lawrence and Archer conclude that protamine insulinate acts more slowly and for a much longer period than ordinary insulin and that a large dose can act for more than two days. It is much weaker in dealing with carbohydrate food and usually cannot prevent hyperglycemia after meals. In contrast, its action on endogenous sugar is nearly as rapid and good as ordinary insulin. It causes less symptoms of hypoglycemia than ordinary insulin, even at the same blood sugar concentration. Protamine insulinate is certainly absorbed more slowly from the subcutaneous tissues. It therefore has qualities which promise great use in severe cases of diabetes with oscillating blood sugars and rapidly recurrent ketosis. On the other hand, it is not strong enough in its action to control ingested carbohydrate, so that the use of ordinary insulin before carbohydrate meals and protamine insulinate in the evening has been advocated and is necessary to obtain full control of the diabetic condition. Another insulin preparation combining the qualities of ordinary and protamine insulinate would obviously be more useful than either. Protamine insulinate, great though its advantage may be in some cases, is not generally obtainable for clinical use in England and is indeed still in the experimental stage.

 *Neuritis in Pregnancy Successfully Treated with Vitamin B₁ G W Theobald—p 834
 Male Hormones and the Question of Accessory Substances Note R Deanesly and A S Parkes—p 837

Treatment of Neuritis in Pregnancy with Vitamin B₁—Theobald successfully treated five cases of neuritis of pregnancy by dietetic measures, four of them solely by the administration of vitamin B₁ (2,250 units) concentrate. All the patients complained of numbness, tingling, pins-and-needles and with the exception of one, of pain which was worse by night. The arms and hands were affected in all the cases, and one side

more than the other. Two of these patients suffered in addition from deficiency of vitamin D in their diets. It is impossible to say whether these symptoms represent an early stage of the "toxic neuritis" of pregnancy. Pregnancy offers opportunities for studying the effects of vitamin and other deficiencies in the diet with the precision of a laboratory experiment. The results reported may be held to support the dietetic deficiency hypothesis of the toxemias of pregnancy.

Glycosuria and Acetonuria in Subarachnoid Hemorrhage. Report of Four Cases E J S Woolley —p 894

Glycosuria and Acetonuria in Subarachnoid Hemorrhage—Woolley reports four cases of hemorrhage into the subarachnoid, in which acetone and sugar were found in the urine, and one presented a clinical picture which resembled in some respects that of hyperglycemic coma. Apart from the fact that sugar and acetone were demonstrated in the urine and that all four illnesses were fatal, these cases had little in common. In the three in which a postmortem examination was made the only common observations were extensive destruction of brain substance and the presence of blood or deeply blood stained fluid in the cerebral ventricles, the site of the hemorrhage was different in each case. In cases 2, 3 and 4 there was no emesis before admission, and in two of them the urine was examined within three hours of the ictus. In case 3 a large meal had recently been taken. It seems, therefore, that the ketonuria is not the result of starvation. The possibility that these patients were the subjects of undiagnosed diabetes mellitus cannot be excluded. There is no evidence in support of such a conjecture, except for the history of lassitude in case 3. It is known that the urine in case 1 had been sugar free a few weeks before the final illness. The mechanism whereby ketonuria is produced in these cases is obscure. It seems that the hyperglycemia following either puncture or pathologic cerebral injury is the result of sympathetic stimulation. It is possible that the ketonuria is the result of a massive increase in the secretion of epinephrine. An alternative theory involves the assumption that there is pancreatic dysfunction as the result of deranged nervous control. It has been shown by Clark that the islets of Langerhans normally receive inhibitory stimuli through the vagi. If the centers of origin of such stimuli were themselves stimulated as the result of hemorrhage, a true diabetes might result. Be the explanation of the ketonuria what it may, it is in the difficulty of diagnosis to which it may give rise that the real interest lies. The coma following intracranial hemorrhage may, in the absence of signs directing the attention to the central nervous system simulate the coma of hyperglycemia so closely that differentiation of the two conditions may be extremely difficult. It is unusual for the odor of acetone to appear in the breath following subarachnoid hemorrhage, but its presence has been described. In none of the cases recorded has altered intra-ocular tension been found. A negative ferric chloride test is common in these cases and, since it must be extremely rare in hyperglycemic coma, it is valuable in differentiating the two conditions.

Immunization Against Measles—Salazar de Souza states that a mild epidemic of measles in Lisbon between June 1934 and May 1935 allowed him to continue his investigations of immunization in measles by means of placental blood. Between June and September he immunized forty-eight patients, some of them with recent placental blood, others with stock blood, and of this number obtained 77 per cent immunization. Further observation of measles developing in those immunized by this means persuaded him to change his technique of preparation of the placental blood. He used sodium ethylmercurithiosalicylate in treating the blood instead of solution of formaldehyde, since he found that the immunizing properties of the serum were less affected by the former. The dose used in this epidemic was from 4 to 5 cc in the first 104 cases and from 6 to 6.5 cc in the last eleven. In the last group, with the higher dosages he obtained 100 per cent immunization while in the first group he had only 75.9 per cent immunization, i. e., twenty-five cases of measles. As a result of these studies he believes that, when large enough doses of properly treated placental blood are used in immunization, the method will furnish a high percentage of good results.

*Acute Venous Thromboses Simulating Arterial Embolism of Limbs M Audier —p 384

Venous Thrombosis Simulating Arterial Embolism—According to Audier, the differential diagnosis between venous thrombosis and arterial embolism of the limbs, while often difficult, is important from the standpoint of treatment and prognosis. A positive diagnosis is based on a group of symptoms resting on the conception that an arterial spasm occurs during the course of acute venous thrombosis. The resultant pain is severe and intense. In the lower limb it involves Scarpa's triangle and radiates along the course of the arteries. It is followed by rapidly developing cyanosis of the foot and lower part of the leg. This cyanosis may precede the development of lividity. The coldness of the limb occurs later and inconstantly. Edema is practically constant and more or less intense but develops rapidly and progressively. The presence of early edema of sudden onset and progressive evolution strongly suggests acute venous thrombosis rather than embolism. After acute thrombosis has been determined with reasonable definiteness it is important to institute treatment rapidly, aimed at the arterial spasm. The most commonly employed method of accomplishing this end is injection of acetylcholine, hyper-elevation of the foot, immobilization, and warming of the involved limb.

Treatment of Gastric Allergies and Erosive Gastritis H Thiers and R Chevallier —p 729

*Treatment of Bronchial Asthma by Insulin Shocks J Wegierko —p 731

Treatment of Bronchial Asthma by Insulin Shocks—About forty patients suffering from bronchial asthma and treated by means of insulin shock have been observed by Wegierko for more than a year. His procedure was to inject 40 units of insulin subcutaneously before breakfast or six or seven hours after the last meal. This was done preferably during an attack of dyspnea from the asthma. Usually sugar was given to the patient as soon as the dyspnea had entirely

disappeared. In less severe cases the shocks were spaced every three to five days. If the dyspneic attacks were more frequent, more frequent shocks were given. In the most severe cases, shocks were given daily and sometimes twice a day until considerable improvement was noted. No bad effects have been observed, but the author has not employed this method of treatment in patients past the age of 70 in those having marked circulatory insufficiency or in cases of pulmonary tuberculosis. From the cases observed it appears that insulin shock stops the attack of dyspnea due to bronchial asthma and that after a number of shocks the character of the bronchial asthma is changed, the attacks of dyspnea are diminished in intensity, and in some cases they disappear completely. The mechanism of action, according to the author, is by means of bronchial dilatation. He believes that the method of treatment may be employed in other disorders characterized by smooth muscle contractions, such as hepatic colic, nephritic colic, migraine and analogous conditions. It may also be useful in allergic disorders. This method of treatment offers a wide field for research.

Spleen in Mediterranean Kala Azar. Clinical, Anatomic and Therapeutic Study. P. Giraud—p. 157

Allergic Disorders of the Gastro-Intestinal Tract.—Urbach states that the disorders which have the character of an intestinal allergy are those in which intestinal, gallbladder or stomach symptoms are produced by allergenic substances. Sensitization may be produced by the oral introduction of the allergen, sensitization of the digestive organs from an allergen introduced parenterally or sensitization from an allergen itself developed in the intestinal canal. Investigation of such disorders involves the taking of a careful history, the relief of the pain or spasm by an injection of epinephrine, and alimentary tests with the suspected allergens. Treatment may be divided into specific, metaspecific or symptomatic specific therapy. Specific therapy may be instituted by the administration of slowly increasing quantities of the known allergen or by desensitization immediately before the meal. Metaspecific desensitization consists in the production of an anaphylactic shock by means of horse serum and in many instances leads to recovery. The symptomatic treatment utilizes preparations of epinephrine in attempting to avoid acute attacks and sometimes favorable results have been obtained by colonic lavage.

*Phagocytic Power of Free Cells in Pleuritic Exudates. G. B. Audo-Gianotti—p. 91

Placental Extracts in Hypogalactia. G. Parmeggiani—p. 97

Clinical Value of Dilution Test as Functional Test of Liver. T. Guido—p. 103

Phagocytic Power of Free Cells in Pleuritic Exudates.—Audo-Gianotti studied the phagocytic power of free cells in pleuritic exudates by means of injections of 1 cc. of a 10 per cent aqueous solution of India ink into the fluid of the pleuritic effusion. The determinations were made in ten patients suffering from exudative pleuritis of varying etiology. The author concludes that certain free cells in pleuritic exudates have phagocytic power, which depends on the type, evolutionary stage and age (phase of degeneration) of the cells. Phagocytosis is intense by cells of a histoid origin (those originated in a reaction of the connective subpleural tissues to the local inflammation) less intense by mesothelial monocytoïd and granulocytoïd cells (those originated in the local reaction of the serous membranes and other pleural structures) and absent in lymphocytoïd cells (those originated in blood and inflammatory cells). The failure of free cells to phagocytose the granules of inert colored substances previously injected into the fluid depends on the presence of lymphocytosis which is a characteristic of exudates of tuberculous pleuritis. The lack of phagocytosis is of diag-

nostic value in tuberculous pleuritis, when the exudates are already formed and have remained in the pleura for a certain time. In these cases the exudates are lymphocytic. Early in the development of tuberculous pleuritis, as well as in acute forms of the disease, however, phagocytosis in the exudates is intense, owing to the fact that the latter are in the period of formation during which the pleura reacts to the inflammatory process with the production of histoid and granular cells. It is only later, on the evolution of tuberculous pleuritis, that the phagocytic power of the exudates disappears through modifications of the cytologic structure of the exudates.

*Acute Polyarthritis in Course of Primary Malaria. Developed near Florence. Case. A. Terzani and Lia Torelli—p. 918

Modern Trends in Therapy of Cardiac Diseases. G. Galli—p. 974

Polyarthritis and Primary Malaria.—Terzani and Torelli state that there is a type of malarial pseudorheumatism which develops in the course of either a primary or a recurrent attack of malaria, early or during convalescence. Arthritis, appearing early in certain forms of malaria with a type of nearly continuous fever, does not modify the febrile curve, which changes to the intermittent type regardless of the presence of arthritis. The polyarthritic symptoms are so predominant that a diagnosis of malaria is overlooked, especially in cases of primary infection with a febrile curve of nearly continuous type. The articular symptoms are different from those of acute articular rheumatism: there is no history of angina, the knee joints are not primarily involved and the joint or joints involved are affected all through the disease. Endocarditis complicates the disease only in exceptional cases. Salicylates fail to relieve the patients. The nature of the disease is determined by the results of the treatment both on the malarial and the articular symptoms rather than by the articular picture which is different from that of malarial neuritis, myositis, osteomyelitis and osteitis. The sojourn of the patients in thermomineral spas is not indispensable to obtain complete recovery, which is obtained, however, in a short time by the administration of an intensive quinine treatment either by itself or in association with salicylates, sulfur or iodine. A case is reported in a man aged 63 who lived in a nonmalarial zone near Florence. The metatarsophalangeal joints were primarily involved and the shoulder joint was intensively and constantly affected all through the disease.

*Contraction of Spleen by Intravenous Injections of Epinephrine in Purpura Haemorrhagica. P. Riolo—p. 603

Metastasis of Vagina from Renal Cancer. Case. G. Manzoni—p. 606.

Contraction of Spleen in Treatment of Hemorrhagic Purpura.—Riolo reports two cases of hemorrhagic purpura with splenomegaly and thrombopenia in which a permanent cure was obtained by repeated contraction of the spleen produced by daily intravenous injections of increasing doses of from 0.01 to 0.1 mg. of epinephrine. The last dose was repeated for twenty consecutive days. After that the blood picture returned to normal and the spleen to its physiologic limits and the patients were permanently cured as proved by follow-up examinations for a period of a year and a half. The author believes that the favorable results of the treatment are due to the fact that it controls both thrombopenia and the lack of tonus of the capillaries of vagal origin which are the two pathogenic factors of hemorrhagic purpura. Epinephrine regulates the functions of the spleen until they return to normal. By means of contraction the organ is forced to expel into the blood stream a greater number of platelets. Epinephrine decreases the lytic activity of the spleen on blood platelets (which is increased in hemorrhagic purpura), stimulates the bone marrow to the formation of a larger number of blood cells and increases the vascular tonus through the sympathetic. The author believes that the treatment is especially indicated in hemorrhagic purpura associated with splenomegaly.

Humoral Theory of Origin of Diseases J Moreno p 988
Diffuse Peritonitis Treatment W Benthin — p 1004

Counting of Platelets in Gastric Cancer—Franco counted the platelets in eighteen patients suffering from gastric cancer. In all the cases the number of platelets per cubic millimeter of blood was normal. The clinical diagnosis of gastric cancer was confirmed in all cases by the evolution of the disease and by the performance of either an operation or a necropsy. On the basis of his results and of the fact that thrombocytopenia is a constant blood alteration in patients suffering from pernicious anemia, the author ascribes value to the counting of platelets in the differential diagnosis of pernicious anemia and gastric cancer and advises further work in this field for verification of his statement.

Injections of Sodium Benzoate in Treatment of Gastroduodenal Ulcer—The work of Beretervide and his collaborators was to verify the value of the intravenous injections of sodium benzoate (Bazzano's method) in the treatment of gastroduodenal ulcers. The authors' patients were placed in two groups, in which the action of sodium benzoate on the gastric secretion and the clinical evolution of patients treated by the injections were investigated. In the first group of patients (ten) the action of the drug on the gastric secretion was investigated by determining the acidity of the gastric secretion obtained by fractional catheterization before and after administration of an intravenous injection of 2 cc of a 25 per cent solution of sodium benzoate. Free and total chlorhydric acidity rose early after the injection in five of the patients, late in two and diminished in three. The second group (sixteen patients) were treated by the administration of a daily intravenous injection of 2 cc of a 25 per cent sodium benzoate solution, varying between twenty and thirty injections. Fourteen patients in this group were suffering from either gastric or duodenal ulcers and two from hyperchlorhydria associated with gastritis. The results of the treatment were negative in eleven patients out of the group of the fourteen with ulcer and favorable in one, and the two other patients disappeared from observation. The treatment gave satisfactory results in one of the cases of hyperchlorhydria and gastritis and failed in the other one. The authors conclude that the intravenous injections of sodium benzoate are not efficient in the treatment of gastric and duodenal ulcers.

Mucous Membrane Changes (Metaplasia) of Uterus in Continuous Administration of Estrogenic Preparations P Grumbrecht — p 525

Thyroid and Pregnancy—According to Pohl the functional activity of the thyroid is slightly increased during pregnancy. The changes in the thyroid characteristic for pregnancy can be produced experimentally by small amounts of the thyrotropic hormone of the anterior hypophysis. Large doses of pregnancy serum produced an effect on the thyroid in experimental animals. Pregnancy causes no thyrotoxic changes. An existing exophthalmic goiter becomes exacerbated by pregnancy in about half of the cases and terminates fatally

in about 6 per cent. Some authors have even observed improvements in thyrotoxicosis during pregnancy. The author emphasizes that the increased thyroid activity during pregnancy is not a pathologic condition but is rather advantageous for the organism, it does not require compensation by other endocrines but helps in the undisturbed development of the growth processes of pregnancy. He stresses that it is inadvisable to refer to the increased thyroid action of pregnancy as a form of hyperthyroidism, for hyperthyroidism indicates a pathologic process.

Deaminating Function of Human Placenta—Botella Llusá shows that the placenta has the capacity to decompose amino acids and to form ammonia and urea. This capacity is found in mature as well as in immature placentas, but its peak is reached during the seventh month of pregnancy. This activity does not necessarily have to be regarded as a vital characteristic at any rate, it is of great interest in the explanation of metabolic disturbances during pregnancy.

Adrenal Cortex and Sexuality—Neumann shows that insufficiency of the adrenal cortex is followed by a reduction of the sexual functions which finally results in gonadal atrophy and, in women, in amenorrhea. He cites the case of a woman with Addison's disease in whom the cyclic sexual function was disturbed. The uterine mucosa was atrophic as in a woman at the onset of the menopause. After treatment with adrenal cortex extract and with *l*-ascorbic acid the menstruation was once more regulated. In addition to an improvement in the general condition there was also a decrease in the brownish discoloration. Hyperfunction of the adrenal cortex may produce premature puberty in children, and virilism (interrenalism) may result in girls of pubertal age. In male persons a change in the sex characteristics is rare. The author describes three cases of hypernephroid blastomas of the adrenal cortex which he observed. In one case he observed a decided virilism which, however, disappeared again following surgical removal of the adrenocortical tumor. Subsequently the woman became pregnant and gave birth to a living child. The author discusses hypernephroid blastomas in the region of the female genital organs and cites three cases. In one the urine produced in infantile mice anterior pituitary reactions I, II and III, but after the operation the elimination of the anterior pituitary hormone decreased because only reaction I was elicitable with the urine. In discussing the manner in which a hyperfunction of the adrenal cortex effects a change in the sex characters, the author suggests that the adrenocortical hormones act on the genital apparatus by way of the hypophysis.

Substance in Serum of Cancer Patients That Binds Melanophore Hormone—Rodewald points out that Trendelenburg and other investigators found that the serum of pregnant women contains a substance which counteracts the melanin diffusing component of the posterior lobe of the hypophysis in its action on the skin of the frog. Further investigations revealed that this inactivation is the result of a binding of the melanophore hormone to a high molecular protein substance. The author observed in experiments that the serum of cancer patients produces an even greater inactivation than does the serum of pregnant women, for, whereas frogs kept on a white ground assumed a somewhat darker shade after a mixture of normal or pregnant serum and extract of posterior pituitary had been injected, the frogs retained an almost unchanged light color when cancer serum was used in the test. Moreover, whereas the inactivating substance in the blood of some normal and of pregnancy bloods can be destroyed by heat (thirty minutes at 55 C), the inactivating substance in

the serum of cancer patients is not destroyed by this treatment. The author tested the inactivation of the melanophore hormone on 385 serum specimens and gives a tabular report of the results. Of the serums from 109 cancer patients, all but four exerted a pronounced inactivating effect. The serum of patients with skin cancers, however, exerted no influence on the melanophore hormone. Among the serums of the 276 patients who had various other disorders but no cancer, seventeen reacted like cancer serums.

Functional Disturbances of Pancreas—Von Bernáth investigated the external and internal secretion of the pancreas in fifty patients with various internal diseases. He examined the external secretion by determining the trypsin and diastase content of the duodenal juice and the lipase content of the blood and urine. To determine the condition of the internal secretion, he studied the course of the alimentary hyperglycemic reaction. He gives the normal values of the various pancreatic ferments and then states his observations on the pancreatic function in various disorders. He found that the pancreatic function was not noticeably impaired in patients with exophthalmic goiter. In diseases of the gallbladder he noted hypofunction of the pancreas. Chronic gastritis is followed by a disturbance of the pancreatic secretion, particularly in the cases in which the gastritis changes into achylia. The studies revealed also that the disturbances in the external and internal secretions of the pancreas are entirely independent from one another.

- Pulmonary Tension Atelectasis and Lung Shrinkage K. Strass—p. 715

Spondylitis Deformans of Cervical Vertebrae—According to Ober, the occurrence of spondylitic alterations in the cervical vertebrae is quite common. The lesions increase with age both in numbers and in severity. A predilection for the male sex was not noted. Three stages of the process are recognizable: (1) isolated calcification of the anterior ligament of a vertebra, (2) deposition of osteophytes at the point of insertion of the anterior ligament and (3) deformity of an individual vertebra. The interdependence of the three stages can be best observed in vertebrae the seat of an advanced lesion. Here one can see as a rule, the three types of lesions with intermediary transitional stages. A vocational predisposition to the disease cannot be established. On the other hand, an etiologic relationship to infections such as furunculosis, gonorrhea, abscessed teeth, osteomyelitis or tonsillitis appears quite probable. The author found no relationship between the severity of the objectively demonstrable anatomic lesions and the objective clinical symptoms and the subjective complaints. The painful subjective manifestations of the disease arising from purely mechanical causes are to be attributed to a superimposed inflammatory process. In the absence of an inflammatory process, most advanced lesions may exist without clinical manifestations. The favorable response to irradiation is explainable on no other than the inflammatory genesis of the clinical manifestations.

Treatment of Dupuytren's Contracture—Maurer presents a study of 200 cases of palmar fascia contracture observed at the Lexer clinic (Munich) during the last decade and among the inmates of the large Munich homes for the aged. He concludes from a review of the literature that of the many etiologic causes advanced trauma and heredity are the ones to be considered. The condition is much more common in men than in women. In his material there were 143 male patients (71.5 per cent) and fifty-seven female (28.5 per cent). The greatest incidence is in people past the age of 50. Chronic occupational traumatization of the palm of the hand is undoubtedly the principal etiologic factor in the causation of this disease. The author found that 55 per cent of his patients were engaged in occupations which exposed their palms to severe chronic trauma of various types such as pulling, pressing or

squeezing, 38 per cent were in occupations exposing the palms to ordinary trauma and 7 per cent were in occupations in which injury to the palmar surface was accidental. Both palms were involved in 107, the right alone in fifty-two and the left alone in forty-one cases. The frequent association with rheumatism, sciatica and gout is probably a coincidence rather than the result of a common "rheumatic or uratic diathesis." The claims made for the hereditary origin could not be verified in the author's material. He could trace this influence in only 10 per cent. He feels that Dupuytren's contracture should be classified as an occupational disease. The most successful treatment is that developed by Lexer, in which the entire palmar fascia with its apparently uninvolved prolongations is removed together with the overlying skin. The defect is repaired either by a free skin transplant or through the use of a pedicled attached flap fashioned out of the skin of the abdomen.

The White Blood Picture in Pernicious Anemia—Hoffmann reports observations on the white blood picture of fifty-seven patients with pernicious anemia. Some of the cases date back to the time before liver therapy was used, but in forty-one cases liver preparations were given. The total number of leukocytes was usually greatly decreased (from 2,000 to 3,500), but an increase in the hemoglobin content was usually accompanied by an increase in the number of leukocytes. In some instances the leukocytes reached highest values after the first administration of liver, but the number usually decreased again with the same rapidity and after that increased slowly simultaneously with the hemoglobin content. Whenever there was no blood crisis or remission, the leukocytes sank to extremely low values. In patients who were not treated with liver there was no increase in leukocytes except immediately after blood transfusions, whereas in those receiving liver therapy increased values were detected in about half of the cases, especially at the onset of a blood crisis. The author discusses the behavior of the various types of white cells with and without liver therapy. His observations indicate that the liver therapy of pernicious anemia exerts a practically specific action not only on the erythropoietic but also on the leukopoietic system. The action of liver preparations on the leukopoietic system is noticeable in all patients in whom the erythropoietic system is likewise improved, but in about 50 per cent of the cases it occurs later than the improvement in the red blood picture. In these cases the leukopenia deviation to the right, lymphocytosis and monocytopenia are not compensated until the red blood picture has become partly or completely normal. The usually rapid increase in eosinophiles which sets in a few days after onset of the liver therapy, is an exception to this rule. In the other half of the cases, a deviation to the left appears soon after onset of the liver therapy and thus proves the prognostic value of the white blood picture. In the latter cases the specific action of liver therapy extends to the white blood picture from the beginning.

Melanogen in Lung and Melanin Formation by Enzymatic Reaction—The Sjöstrands showed that the lungs of mammals and birds contain a type of cell characterized by its iron content and profuse granules, which consist of at least three different substances which partly seem to change into one another. In the course of this transformation, which is dependent on the accumulation of blood in sinuous vessels, there develops a product which under the influence of certain aldehydes by an enzymatic reaction, may be changed into a substance showing the behavior of the natural melanins. This substance can be obtained from the lungs in considerable quantities.

Studies on Aujeszky's Diseases (Pseudohydrophobia)

—Gerlach and Schweinburg describe experimental studies on pseudohydrophobia, which revealed that the virus of Aujeszky's disease is a latent neurotropic, filtrable virus. It is related to the virus of hydrophobia but differs from it fundamentally in many points. It seemed to be somewhat less resistant than the virus of hydrophobia to drying and chemical agents. The eight strains of virus of Aujeszky's disease which the authors examined differed considerably as regards virulence and incubation, but they all produced the clinical aspects of Aujeszky's disease. It proved possible to transmit the virus to experimental animals by all known modes of infection. Oral infection succeeded only in exceptional cases. In some cases the disease was transmitted by mere contact and occasionally by biting. After the disease has become manifest, the virus is always found in the brain and quite frequently also in the parenchymatous organs and in the blood. The virus was not demonstrable in the urine and in the stool, but in one case the disease was transmitted by means of the saliva of an infected cow. In rabbit passages the virus of Aujeszky's disease was constant but successive passages in guinea-pigs and in rats reduced the virulence and a subsequent rabbit passage increased the virulence again to the original degree. The immunization of healthy animals against Aujeszky's disease did not succeed entirely. Animals that have had an attack of the disease have a considerable immunity, which persists for at least nine months and perhaps longer. The virucidal action of the serum of these animals is only slight, but they tolerate subcutaneous and interperitoneal immunization quite successfully and thus aid in the production of highly virucidal serums. The animals thus treated have an immunity also against cerebral infection with the virus of Aujeszky's disease, but they are not in the least immune to hydrophobia. The virucidal serums are strictly specific in that they destroy even the strongest virus concentrations of Aujeszky's disease, but they do not neutralize even attenuated solutions of hydrophobia viruses. On the other hand animals that are immune to hydrophobia are not immune to Aujeszky's disease.

Traumatic Pneumonia—Reinberg and Kaplan are of the opinion that all pneumonias develop on the basis of an obstructive pulmonary collapse. After a bronchial lumen has been obstructed, the air in the corresponding pulmonary lobe is completely absorbed by the passing blood in about two hours. The authors mention the various factors that may cause obstruction of the bronchial lumen and then discuss the pulmonary mechanisms that aid in opening the bronchial lumen. They show that vigorous functional activity is of great importance in the prevention of pneumonia and that this is accomplished best by respiratory gymnastics in the sitting position and by carbon dioxide inhalation. They say that in this manner they were able to reduce the incidence of postoperative pneumonia as well as the pulmonary complications of typhus. In discussing traumatic pneumonia, the authors point out that in rib fractures, for example, the great pain at the sites of fracture leads to restriction of the functional activity and thus to deflation of the lung. During this state of deflation a small quantity of bronchial secretion readily obstructs the lumen and since coughing is suppressed on account of pain the secretion quickly accumulates. The authors realized that in order to facilitate respiration it was necessary to counteract the pain. They did this by injecting from 10 to 15 Gm of a 1 per cent solution of procaine hydrochloride at the site of the fracture. This measure has a prompt effect. The existing cyanosis disappears and the patient is able to expel the secretion by

coughing and to breathe properly. The authors employed this treatment in about forty patients with thoracic injuries, and in this manner they were able to prevent pneumonia.

Substances E. Lowy—p 595

Specific Treatment of Erysipelas—Neuber gives his attention chiefly to the use of convalescent serum. He found it advisable to give polyvalent convalescent serum, that is a mixed serum from six or eight patients. Since the active substances in the convalescent serum quickly lose their efficacy at room temperature as well as in the iccbox, he considers storage in the frozen condition advisable. He administers the convalescent serum by intragluteal injection. The serum is given at intervals of two or three days and in increasing doses. At the first injection between 40 and 80 cc is administered. The author found that after the larger doses (from 60 to 80 cc.) the fever subsides more rapidly than after smaller doses (30 or 40 cc). He observed also that the serums from patients who had not been given convalescent serum were more effective than those of other patients. Because of this he restricts the treatment with convalescent serum to the severe cases and uses as donors the patients who have the milder forms. He admits that mild relapses appear occasionally after treatment with convalescent serum however, they usually disappear again spontaneously in a comparatively short time, but in order to avoid them he considers it advisable to give a few additional serum injections after the first attack has subsided. If the supply of convalescent serum is exhausted, after-treatment with chemotherapeutic substances (arsphenamine, quinine and so on) is advisable.

Arterial Hypertension and Thyroid Function—Schur discusses the theories of the pathogenesis of hypertensive tachycardia. He shows that the majority of cases are accompanied by a considerable increase in the erythrocytes with vital granules. Tachycardia as well as the number of these erythrocytes usually decreases following the administration of di-iodotyrosine and increases again after this medication is discontinued. The author thinks that these observations are a further argument in favor of a hyperfunction of the thyroid in these cases. He agrees with J Bauer who assumes that an increased blood perfusion of the thyroid is responsible for this hyperfunction.

- *Rehabilitation of House Fly H Pach—p 517

Experimental Cancer Immunity—Besredka and Gross review some of the literature on this problem and describe their own experiments on rabbits. They reach the conclusion that rabbits are readily immunized against epithelioma. In order to produce this immunity it is sufficient to give an intracutaneous injection with a freshly prepared tumor suspension. The intracutaneous tumor that is produced in this manner soon becomes resorbed and the animal becomes immunized against epithelioma. This immunity is specific, solid and permanent, but it is not transmissible, that is, it is of a cellular nature.

Flies and Transmission of Typhoid—Pach directs attention to a former report in which he gave evidence to the effect that the theory according to which the house fly (*Musca domestica*) transmits typhoid is no longer tenable because it contradicts the biology of the house fly and the epidemiology of typhoid. In this report he cites additional studies that were carried out under the supervision of the Hungarian hygiene institute and which he thinks are likewise evidence against the widely accepted theory of the carrier function of the house fly in the transmission of typhoid.

Leech Therapy of Embolic Processes—According to Blumental, the leech therapy of thrombophlebitis was proposed by Termier in 1922. In 1884 Haycroft found a substance in the secretion of the buccal glands of a leech to which Jacoby gave the name "hirudin." Experiments *in vitro* demonstrated that hirudin retards coagulation of the blood and that this effect is caused by its antithrombin action. It destroys the fibrin ferment without affecting the fibrinogen. Straaten believes that this effect is due not only to the anticoagulant action of hirudin but to prolongation of the bleeding time as well. Slowing of coagulation begins to take place from six to eight hours after the application of the leech, reaches its maximum in about thirty hours, and returns to normal in from forty-eight to fifty hours. The effect of hirudin is limited to a relatively small area in the vicinity of the applied leech. The rapid disappearance of edema following the application of leeches in acute thrombophlebitis is believed to be due to its lymphogenic action (Straaten). In addition, it possesses a bactericidal action which explains the rarity of infections after application of leeches to a skin not treated by antiseptics. A leech is capable of sucking from 15 to 20 cc. of blood. The puncture wound, after the leech has fallen off, continues to bleed for several hours. The amount of blood thus lost amounts to from 50 to 75 cc. The author sums up the effect of leech therapy on a thrombophlebitic process as follows: 1. Extension of the thrombotic process is arrested by the anticoagulant and absorbing action of hirudin. 2. The associated edema rapidly diminishes and disappears because of a lymphogenic action of hirudin. 3. The process is further favorably influenced by leukocytic and bactericidal properties of hirudin. As a result, the inflammatory process is aborted, the pain subsides and the infiltration is rapidly absorbed. The method to be followed in treating thrombophlebitis is to apply leeches in pairs alongside the inflamed vein about 2 cm. away from it on both sides of the vessel at intervals of from 4 to 6 cm. From six to ten leeches may be applied. Hirudinization may be repeated every forty-eight to sixty hours. Two or three treatments are, as a rule, sufficient, but in exceptional cases from five to six may be required. The author treated thirty-two cases of acute thrombophlebitis, seven of which developed after an operation and two after delivery, three followed an infection, ten developed on a basis of varicose dilatation of veins; in five the process was an acute flare-up of a chronic thrombophlebitis, three were cases of acute inflammation of hemorrhoidal nodes and three were cases of acute thrombophlebitis of undetermined cause. The results were gratifying in all cases. The author concludes that hirudinization is the most effective treatment for thrombophlebitic processes.

Treatment of Tetanus—Grasmik treated three cases of tetanus by intraspinal injections of from 4 to 5 cc. of a 3 per cent solution of phenol and noted good results. Two of the patients survived and one died. In the next six cases he injected the same amount of phenol together with 1,500 units of antitetanic serum. All patients recovered. The difficulty of the intraspinal method in the presence of opisthotonos is met by a preliminary administration of morphine and local anesthesia. Objective improvement was noted several hours after the injection. From his animal experiments the author concluded that treatment of tetanus with injections of phenol alone is not permissible. The antitetanic serum is effective only when introduced into the spinal canal. The combination of phenol with small doses of the antitoxin gives good results. The role of phenol is that of a nonspecific irritant of the central nervous system while the antitoxin exerts its specific influence. Thus the combination therapy renders it unnecessary to employ large doses of the antitetanic serum.

 Pulmonary Suppuration V. V. Lavrov—p. 230
 *Embolism of Superior Mesenteric Artery N. S. Okun—p. 240

Embolism of Superior Mesenteric Artery—Okun reports eleven cases of embolism of the superior mesenteric artery. There were eight instances of this condition among 230 necropsies. The condition was not diagnosed in a single case before the operation or necropsy. The etiologic factors in nine cases were acute, recurring, ulcerative, vegetative and chronic endocarditis and atheromatosis of the aorta. While the diagnosis is difficult, the presence of pathologic alterations in the cardiovascular system constitutes a valuable aid in the diagnosis of the condition. The pathologic alteration in the intestine is that of a hemorrhagic infarct and only rarely that of an anemic infarct. The clinical manifestations are those of diarrhea, ileus, or a combination of the two. Three of the author's cases were characterized by diarrhea, three presented a picture of intestinal obstruction, one presented symptoms of both diarrhea and ileus, while the rest presented a vague symptomatology. All patients died. An early operation with resection of the involved intestine is the only method offering a possibility of cure.

- *Number and Percent Apportionment of White Blood Corpuscles in Suppurative Coloproctitis O. Moltke—p. 83
 Clinical Investigations into Action of Protamine Insulinate. A. B. Krarup—p. 97

White Blood Corpuscles in Suppurative Coloproctitis—Of the twenty cases of suppurative coloproctitis examined by Moltke, seven proved fatal. In these leukocytosis was sometimes found, but there was a constant considerable, sometimes exceptionally high, increase in the immature neutrophil cell elements, both relatively and absolutely. In eleven cases of more or less grave disorders, none fatal, the values could rarely be designated as leukocytosis, in most cases there were slight shiftings to the left. Two patients, examined during periods of remission, showed neither leukocytosis nor shifting to the left. The author consequently considers constant more marked shifting to the left (i. e., relative values above 25 per cent and absolute count of more than 2,000) an important and grave prognostic sign. Reduction in shifting to the left is observed coincident with clinical improvement. A relative and absolute leukopenia occasionally appears in grave cases, it is apparently affectable by blood transfusion. Eosinophilia may occur, but it is not a constant phenomenon in suppurative coloproctitis.

- *Orogenic Meningitis with Especial Regard to Pathology of Disorder H. Björk—p. 304

Orogenic Meningitis—Of Björk's twenty-nine cases of orogenic meningitis in acute otitis in which treatment was administered from 1930 to 1935, sixteen represented primary and thirteen secondary meningitis. Of the former, thirteen were tympanogenic (four fatal) and three labyrinthogenic (two fatal). Of the latter, eleven resulted from sinus thrombosis (six fatal) and two from brain abscess (both fatal). Two of the fourteen deaths were caused by other complications, and the mortality from meningitis was thus 44.4 per cent. The nine cases in which there were bacteria (streptococci) in the cerebrospinal fluid were all fatal. The author concludes that meningitis in connection with acute otitis originates equally often from primary and from secondary infections. The great majority of cases are due to a tympanogenic or a sinusogenic infection. Disturbances in development play an important part in the progression of the disorder to the meninges. In twenty-six of his twenty-nine cases there was an abnormally wide or an obstructed pneumatization.

TRENDS IN AMERICAN OBSTETRICS DURING THE FIRST THIRD OF THIS CENTURY

CHAIRMAN'S ADDRESS

LYLE G McNEILE, M D
LOS ANGELES

Although many notable advances and changes have been made in the practice of general medicine and surgery during the present century in no specialty have there been more drastic changes than in obstetrics.

In order to obtain a clear conception of the evolutionary changes and tendencies in obstetrics one must first glance at the conditions that existed at the end of the nineteenth century. It must also be fully realized that much of the progress made in the present century is the direct result of the pioneer work of Cederschjold, Holmes, Semmelweis, Pasteur, Lister, Smellie, Tarnier and many others. The assembled facts from the many traditions and observations of these pioneers have in many instances been "rediscovered" and reapplied.

At the beginning of the century the overwhelming majority of women in the United States and other countries were delivered by midwives, in the home. The rich could command the services of one of the few specialist obstetricians who gave some antepartum care but usually delivered the patient at home, the labor, nevertheless, being allowed to follow its natural course. For the indigent, there were in several large cities, lying-in hospitals, usually maintained for the purpose of providing clinical material for a teaching institution. Brodhead¹ records that the pregnant women in the Sloane Maternity Hospital in New York were systematically examined and that pelvimetry was a routine procedure. Vaginal examinations were freely made preceding and during labor. No sterile gowns or gloves were used.

Bill² states that in Cleveland twenty-five years ago there was no physician who limited his practice entirely to obstetrics, and there was very little obstetric hospitalization. Most of the deliveries were done by midwives, the physician being called only when the midwife encountered unusual difficulty. This should be compared with records of the same city in 1930, when 55.7 per cent of the babies were born in hospitals and approximately 45 per cent of the deliveries were made by specialists or under their supervision. During the past ten years the number of deliveries done by midwives has been reduced to less than 6 per cent.

Thus, at the beginning of this century every general practitioner had perforce to be an obstetrician, but at this time the new fledged doctor obtained his diploma to practice with little or no actual experience in clinical obstetrics. There were at this time not more than a half dozen medical schools that maintained lying-in hospitals in which medical students could witness deliveries, and the student who had actually delivered one or two women before he was graduated was considered very lucky.

Even with this, thirty-five years ago it was considered that there was but little room for improvement in the art of obstetrics. Versions, forceps operations and maneuvers for the correction of malpositions were well known to and practiced by experienced physicians, but in those days it was more generally recognized than at present that even difficult labors very often ended in spontaneous delivery if the woman was allowed a sufficiently long labor.

THE DAWN OF NEW OBSTETRICS

However, several things were happening that were destined to alter the course of obstetrics. The development of asepsis and the perfection of surgical technic in Germany had, even before 1900, made cesarean section a much more frequent operation than formerly. Norris³ in 1899 pointed out that the successful obstetrician of that day must be a thorough surgeon and a competent gynecologist, because cesarean section and other obstetric operations were being performed with almost startling frequency. The conception of Krong in 1894 and of Williams in 1898 that the vagina of every pregnant woman who had not been examined vaginally was sterile was new, as also was the general recognition that so-called puerperal fever was puerperal infection by the streptococcus. There occurred at the beginning of the century another innovation, the introduction of the use of rubber gloves for vaginal examinations and during delivery. A spirit was being aroused to do something actively to relieve the pain and the dangers of childbirth and to safeguard the child, as compared with the old laissez-faire policy of letting nature take its course. This was the fundamental spirit of the new tendency in obstetrics about the beginning of the twentieth century.

CAUSES THAT CONTRIBUTED TO THE CHANGED TENDENCIES IN OBSTETRICS

The principal causes that acted as contributing factors to bring about a change in the practice of obstetrics were first, the scientific advances in medicine and surgery, second, and very important, the demands of the American woman, third, propaganda by surgeons and by those interested in making obstetrics a specialty, and, fourth, social, economic and biologic factors.

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1936.

¹ Brodhead G. L. Modern Obstetric Technic Compared with the Technic of Twenty Years Ago, *Am J Obst* 78:305, 1918.

² Bill A. H. The New Obstetrics, *Am J Obst & Gynec* 23:155 (Feb) 1932.

³ Norris R. C. *Obstetrics Prog Med* 3:323-422, 1899.

In regard to the first, the great impetus to surgery through the development of asepsis vastly extended its field and was bound to have its reflex in cesarean section and other operative procedures connected with obstetrics. Symphysiotomy, pubiotomy and episiotomy were among such procedures which were early popularized. From the medical field came the development of several important drugs, such as solution of posterior pituitary, which was much more rapid in its action and more reliable in producing good uterine contractions than was the ergot of the day. It was not until hundreds of ruptured uteri had been reported, however, that the danger of pituitary preparations was recognized, and their real value, the control of hemorrhage after delivery, generally accepted. From the medical group also came the rapid development of methods of analgesia and anesthesia, the former to control pain during labor, the latter to render operative procedures painless. Steinbuechel introduced the method of so-called twilight sleep into German obstetric practice in 1902. Although in its original form it was dangerous and did not survive for long, it had a very definite influence on the development of the more acceptable present-day methods.

The second factor, the demands of the American woman, is one that has not been sufficiently stressed by those who criticize modern obstetrics and its results. The American woman was educated by lay propaganda to know that scientific medicine could spare her the pangs of labor without sacrificing her child. Even if physically as well as or better able to bear pregnancy and labor than generations before her, she demanded and has continued to demand and to insist that childbirth be accomplished without pain. She does not want the old method of letting nature take its course. Moreover, if she is told that the newer methods are accompanied by an increased morbidity and mortality both for herself and for her child, she ignores such possibilities and accepts all risks of anesthesia and operative procedures provided she remains in oblivion throughout the ordeal. The old generation of women looked with fear and terror to the time of labor. Today a primipara, secure in the knowledge that she will receive anesthesia and analgesia, merely looks on childbirth as an incident. If this present-day attitude is abnormal, I believe that the fault lies with the obstetric profession, which has allowed lay propaganda to be broadcast for more than twenty years and yet has not, except in one or two instances, attempted to educate the public through its own medium, the lay press.

The third factor—propaganda by surgeons and specialists in obstetrics—was a logical consequence. Women demanded a rapid, painless labor. Anesthesia and analgesia caused uterine inertia, which in turn required some type of operative intervention. To execute these procedures properly, men specially trained in operative obstetrics were necessary and answered the call. These men very naturally raised their voices in favor of their own procedures, and today it is a controversial question as to whether or not they were not, at least to some extent, right. The rational use of anesthesia and instrumentation, entirely apart from the demand for it by prospective mothers, may be the better obstetric procedure. In any case the old-fashioned practitioner who patiently sat by the bedside for long hours was ruthlessly pushed aside and his methods were scouted by the profession and the public alike.

The social, economic and biologic factors tending toward changes in American obstetrics were many. There was the great extension in urban communities of the flat or small apartment, which made hospitalization of the woman at term a necessity. Again, hospital delivery began to be looked on by women as the correct style, there is social etiquette even in obstetrics. Economically, for a large percentage of the people, free dispensaries, even free hospital service, free public health welfare clinics and many other organizations literally pushed the pregnant woman into the newer methods rather than to allow her to remain at home and call the midwife at the onset of labor. Biologic factors, such as voluntary birth control, affected obstetrics only by reducing the birth rate. But a biologic factor such as the tendency toward fewer babies and the limitation of progeny even by abortions, self induced or otherwise, must have a very definite effect on obstetrics. This, however, is an important phase which time will not permit me to enlarge on here. Another biologic obstetric factor in the United States is the mixture of races. It is well known that pelvic measurements vary in different races and that such studies as have been made of fetal head measurements show that they too manifest similar variations. Furthermore, statistics prove that in races having smaller pelvises the head measurements too are proportionately smaller. This accounts for the frequency of dystocia due to disproportion in mixed marriages with women having smaller pelvises and may be important in explaining the increased incidence of dystocia in America.

De Lee⁴ puts the whole matter of the new tendencies in obstetrics very succinctly:

The woman nowadays demands a safe labor, freedom from unnecessary pain, a reasonable length of labor, and when she arises from confinement a complete *restitutio ad integrum*. She also demands a healthy baby, undamaged by conditions affecting it during pregnancy and free from the effects of traumatism during labor. Modern obstetrics can give the woman nearly all of these things and people are willing to pay for them.

TRENDS OF THE NEW OBSTETRICS

The outstanding trends in American obstetrics since the beginning of the century would doubtless be seen in a different light by each obstetrician who paused to consider them. To me they may be placed under five headings: first, the changing ideals in obstetric education, second, to regard pregnancy and labor as pathologic rather than physiologic processes, third, to make parturition easier for the mother, fourth, to make obstetrics easy for the obstetrician, and, fifth, to eliminate the midwife.

OBSTETRIC EDUCATION

It is impossible to think of the development of the scientific background of obstetrics during the first quarter of the twentieth century without thinking of the late John Whitridge Williams. Professor Williams realized that real knowledge of the physiology and pathology underlying all the phases of reproduction was absolutely essential before obstetrics could ever hope for a place among the recognized specialties. Slemmons⁵ says: "Research, teaching, and the care of the sick were effectively blended in [his] department

⁴ De Lee J. B. *Progress Toward Ideal Obstetrics*. Am. J. Obst. 73: 407 (March) 1916.
⁵ Slemmons J. M. *The Academic Career of John Whitridge Williams*. West. J. Surg. 44: 47 (Jan.) 100 (Feb.) 1936.

through the chief's inherent talent for organization, and it is not easy to say in which of these fields he was most gifted."

During the same period, Cragin, Burton Cooke Hirst, Edgar and several other outstanding teachers of obstetrics developed the first specially constructed maternity hospitals and clinics in the United States and instituted the form of clinical teaching that is generally used today. There was a definite trend toward adequate obstetric education.

Never in the history of American obstetrics had there ever been a real attempt made to pause and to take stock of the real status of obstetric education until the third White House Conference, called by ex-President Hoover to meet in 1930. While previous White House conferences had been held, they were concerned chiefly with the problems of the dependent child, the social and economic status of the child, supplemented by its health and that of its mother. Under the able leadership of Fred L. Adair, who was assisted by the outstanding leaders in obstetric education and many other subjects which are directly or indirectly related to maternal welfare, the 1930 White House Conference assembled tangible facts which showed the unenviable state of obstetric education, the high maternal mortality in this country, and many other facts which were destined to lower snug satisfaction with the existing conditions. The conclusions of the committee were not destructive, however, for they pointed out causes in many instances and suggested very definite remedies. In obstetric education the necessity of combining the departments of obstetrics and gynecology was stressed, and this is being accomplished in the medical schools. The necessity of providing adequate clinical material in obstetrics for undergraduates and for careful supervision of clinical teaching was shown. The value of additional facilities for furnishing postgraduate obstetric education was emphasized, particularly in its relation to infant and maternal mortality. The development of the motion picture as a means of teaching clinical obstetrics was pointed out as a thoroughly satisfactory method of providing teaching material in those schools which lacked adequate clinical material. The use of films, properly edited and directed, presents such great possibilities that I am inclined to regard their development as a teaching method as a reasonably well established trend.

The report of the subcommittee on Factors and Causes of Fetal, Newly Born, and Maternal Morbidity and Mortality has led to a definite trend which may have the greatest influence in the reduction of morbidity and mortality. I refer to the various investigations of the local problems relating to obstetrics, a consideration of their causes and their treatment, undertaken by many medical societies, health departments and allied agencies. The problem of maternal mortality in the United States had occupied a major position in the program of the Children's Bureau since its organization, and numerous studies had previously been made by interested agencies. No general interest had been shown, however, until the report of the Committee on Maternal Mortality of the New York Academy of Medicine was released to the daily newspapers in abstract form under the title "Why Women Die in Childbirth," Nov. 20, 1933. This report brought forth a storm of protest from the medical profession, but the disinterested observer would be inclined to believe that the protests arose from the manner of its

publication rather than from its major conclusions. A very definite trend was created, i. e., the investigation of each obstetric death and the responsibility for its occurrence by local and sectional societies, health departments and others in many large sections of the United States. On the West Coast, the Pacific Coast Society of Obstetrics and Gynecology is investigating every such death occurring in Washington, Oregon and California. The paper of Dr. William Benbow Thompson⁶ on "Caesarean Section in Los Angeles County" is a good example of the scope of such a report. It is inconceivable to me that such investigations can fail during the next two decades to exert a favorable influence on both morbidity and mortality.

The report of the subcommittee on Basic Sciences and Their Relation to Maternal and Fetal Problems stated: "The entire fund of present information concerning what is desirable in safeguarding the health of mother and child rests, with a few exceptions, upon definite underlying principles rather than upon empiric procedure." There is definite evidence of a trend in medical schools and among research workers toward research in the problems peculiar to obstetrics. The greatest progress, however, seems to have been made in the study of the endocrines and in the development of certain drugs such as anesthetics, analgesics, oxytocics and antiseptics, because, in these fields, money has often been made available by commercial companies in the understandable expectation of profiting by the research.

IS PREGNANCY A DISEASE OF NINE MONTHS' DURATION?

There are apparently two well developed schools of thought in regard to the question: Is pregnancy a disease of nine months' duration? Williams in 1926 stated: "I am inclined to suppose that many practitioners in urban communities have been led astray by the teachings of those who regard labor as a pathologic rather than a physiologic process, with the result that interference upon insufficient indications is frequently undertaken by those who do not fully appreciate the risk involved." De Lee said in 1927: "Can a function so perilous that, in spite of the best care, it kills thousands of women every year, that leaves at least a quarter of the women more or less invalided, and a majority with permanent anatomic changes of structure, that is always attended by severe pain and tearing of tissues, and that kills 3 to 5 per cent of children—can such a function be called normal?" The conservative or old school consider pregnancy and labor as natural and normal and not as a general rule to be interfered with, the new tendency regards pregnancy and labor as subjects for therapeutic measures from onset to termination, any method, surgical or otherwise, that will eliminate the discomfort, pain and/or danger of these processes is justified.

The trend during the past fifteen years has been very definitely toward increased operative intervention. Whether or not this trend will continue is debatable.

TREND TOWARD MAKING OBSTETRICS EASIER FOR PATIENT AND PHYSICIAN

These trends have been characterized by a number of procedures which may be summed up in a few words as shortening the time of labor by instrumental or operative delivery under anesthesia.

⁶ Thompson W. B. Caesarean Section in Los Angeles County read before the section May 15 and to be published in THE JOURNAL.

Here, of course, I am not speaking of therapeutic abortion but of what is commonly accepted as labor at or near full term. The present operative furor in obstetrics began with the introduction of the obstetric forceps and the substitution of the physician for the midwife in obstetrics. It has gained impetus with every generation. In the first two decades of this century there was a tremendous increase in forceps delivery, delivery by internal podalic version, by abdominal cesarean section, by low so-called prophylactic forceps with episiotomy, by low cervical cesarean section, and more recently the routine induction of labor by artificial rupture of the membranes at estimated full term.

So far back as 1899 Norris³ wrote "The radical tendency (to perform cesarean section) which has recently been manifested by articles on this subject by men high in the profession I cannot but regret, and I can see in this a dangerous teaching which will be exceedingly apt to lead to unhappy results." The unhappy results are strikingly shown by Plass⁷ whose figures in 1931 showed an increasing year-by-year incidence of cesarean sections in representative American hospitals and who presented mortality figures for cesarean operations in large sections of the population, which varied from a low of 4.2 per cent to a high of 16.1 per cent.

In 1920, at the meeting of the American Gynecological Society, De Lee⁸ described his "prophylactic forceps" operation, in which he recommended, particularly in primiparas, that, when distention of the perineum was evident, episiotomy be performed and the patients delivered with forceps. In spite of very pronounced opposition, his method has had a very strong following.

Available statistics would indicate that the maternal mortality from forceps operations is low.⁹ Maternal morbidity, as well as fetal morbidity and mortality after forceps, has been shown rather definitely to be increased.

Internal podalic version received an extraordinary impetus in 1920, when Potter¹⁰ of Buffalo introduced some modifications and expressed the opinion that every obstetric patient should be delivered by this method at the end of the first stage of labor if feasible so as to avoid the discomfort of the second stage. Williams¹¹ tritely remarked that possibly Potter was right and the rest of the obstetric world was wrong, and Polak¹² said regarding Potter's report of 1,113 labors with 920 versions and eighty cesarean sections, with a fetal mortality of 6.7 per cent "His operative incidence is so much greater than has been shown to be necessary, and his fetal mortality so much higher, that I cannot see on what ground he claims endorsement for his procedure." These innovations, however, in spite of the condemnation which they have received, already have had some distinctly beneficial effects. Today forceps are used more frequently than formerly, and yet far more safely. The high forceps operation has

been abandoned in favor of version or of low cervical cesarean section. The use of low forceps has become very common, and its advocates have been able to show real benefit when proper conditions are present and good technic is used. Potter's technic has resulted in vastly improved results in the treatment of breech presentations in my clinic, and his advocacy of podalic version has been an important factor in the elimination of the high forceps operation, it having been definitely proved that podalic version is a far safer procedure than high forceps.

The obstetric operative incidence in hospital practice in the United States is said to vary from 10 to 30 per cent of all deliveries as compared with 4 per cent in European and other countries in which midwife delivery is the common practice. Epstein and Fleischer¹³ found that the morbidity risk in operative obstetrics, as compared with nonoperative, was in the ratio of 5 to 1 and that the maternal mortality risk was 30 to 1. For the year 1929 Holmes¹⁴ found that 445 hospitals with 221,859 deliveries reported 46,946 operative terminations of pregnancy or labor.

It has been noted that the present trend toward operative intervention in obstetrics began with the introduction of the obstetric forceps and the elimination of the midwife and has gained impetus with each succeeding generation.

I shall quote the opinion written by Francis H. Ramsbotham of the Royal College of Physicians, London, England, in 1841 and compare it with the opinion of E. D. Plass, written in 1931, regarding this operative furor.

Ramsbotham said

Although in skilful, and especially discriminating hands, obstetric instruments must be regarded as great blessings to the suffering sex, yet it is a question with some practical men, whether by their unnecessary use they have not produced on the whole more injury than good. During the long reign of barbarous surgery, there is ample evidence to prove that operative interference was often most unjustifiedly had recourse to, and there is good reason to fear that many women have dragged out a wretched existence to the end of their days, the miserable victims of impatience, ignorance, or violence. In no few instances, the child, if not the mother's life has been sacrificed, when patience, perseverance, and a proper reliance on the natural powers, were the only obstetric auxiliaries required.

I would not have it thought, by these observations, that I am unable to appreciate the advantages sometimes resulting from instrumental aid, or that I would draw an argument against a valuable measure from the possibility of its abuse. I know too well that nature sometimes fails, and occasionally both the mother and her offspring would be overwhelmed in one common fate unless art stepped in. But I would endeavor to impress deeply upon the mind of the young practitioner, that urgent necessity alone will warrant him in taking an obstetric instrument in hand and that, when a choice is allowed him, he should leave nature to accomplish her own purpose, provided, indeed, that he can with safety trust her.

In his practice he will find it much more difficult to determine the time when instrumental aid may have become necessary, than to administer that aid, and unfortunately he will find the most deadly means most easy of application. Many times also, he may almost be persuaded, against his own opinion to the adoption of these means, by the urgent and unceasing solicitations of the patient. I would entreat him neither to allow these considerations to weigh with his judgment

ment, nor to let that less worthy motive, a wish to take advantage of the éclat likely to result from a successful operation, tempt him to act contrary to his own feelings of propriety

Nearly 100 years later, Plass¹ said

The marked increase in forceps deliveries in this country is accounted for largely by the performance of "convenience" operations. Although they have been dignified by the name of "prophylactic forceps," there is no good evidence that they prevent anything but loss of time on the part of the operator. The increased use of cesarean section is merely part of the modern operative furor, but from the standpoint of maternal mortality probably the most important since by conservative estimate the death rate is between 5 and 10 per cent

Thus two men, both well qualified to speak on the subject but living in widely separated countries and writing a hundred years apart, give the same advice. But in spite of the unanimity of opinion on the part of those who are best qualified to express the facts, and in spite of the commonly accepted obstetric axiom that any intervention with normal labor carries a definite risk, neither the operative incidence nor obstetric mortality is being lowered

In spite of this gloomy picture of radical obstetrics during the first third of the century, several trends in favor of conservative obstetrics are apparent. The very great extension of the antepartum care of the pregnant woman has been outstanding. This has been in great part due to the efforts of the Children's Bureau. Such antepartum care not only has resulted in stricter supervision of the hygiene of pregnancy but also has stimulated the early recognition of toxemias of pregnancy, deformed pelvis, and many medical complications of pregnancy which were formerly unrecognized. In eclampsia, particularly, a very definite trend away from radical measures, such as routine cesarean section in favor of conservative measures, is very apparent. The discovery of insulin has completely changed the prognosis for the diabetic patient who becomes pregnant, the management of cardiac patients during pregnancy has undergone great changes, and the introduction of blood transfusions in the treatment of the obstetric hemorrhages has been of incalculable benefit.

Efforts to treat obstetric complications as such, rather than to terminate the pregnancy, are continually increasing.

THE ELIMINATION OF THE MIDWIFE

The fourth trend in American obstetrics during this century has been to eliminate the midwife as a factor in obstetrics. De Lee,¹⁵ whose great influence on American obstetrics is acknowledged by all, has been consistently opposed to her.

In 1902 Hirst¹⁶ recommended "that the average obstetrical case be entrusted to a highly trained, well informed, skilful, and experienced nurse, the physician being called to repair the injuries of childbirth, to deal with any complications or abnormalities that might arise, to make perhaps routine visits, and above all to make the final examination at the end of puerperal convalescence." Hirst probably was thinking of the maternal mortality in Holland and the Scandinavian countries, where the maternal death rate is the lowest in the world. In these countries 85 per cent of the deliveries are done by midwives who do not use forceps

or other instruments and who are instructed and supervised by physicians. He was also thinking of home deliveries and did not, of course, visualize the vast increase in the number of hospital deliveries.

Figures can be given¹⁷ that show the relatively high and the relatively low maternal mortality in cases attended by midwives, but such figures are not at all conclusive. The Medical Advisory Committee of the Children's Bureau in commenting on maternal mortality in fifteen states says "Figures given in the report would indicate that, although the midwives played a part in the mortality, they could not have been responsible for any large proportion of the deaths because they attended a relatively small proportion of the cases."

Regardless of arguments for or against the midwives, they are being eliminated in by far the greater portion of this country. It seems probable to me that the real reason for this lies in the general recognition of their lack of training, as well as to the already mentioned demand of the American woman for a short and painless labor.

APPARENT TRENDS CHARACTERIZING OBSTETRICS IN PRESENT CENTURY

Can any lesson be drawn from a consideration of the apparent trends which have characterized obstetrics in the United States during the present century? Bill² says

It would seem that the most marked feature of present-day obstetrics is the fact that there is a distinct spirit of activity, of being ever alert to do something to relieve the patient and to safeguard her and her baby from the dangers which are ever associated with labor, as against the older policy so often expressed of letting nature take its course.

The new school of obstetrics is without doubt here to stay. There seems to be a feeling of skepticism on the part of many obstetricians, who, while admitting the advantages to the patient of such methods when properly carried out, doubt the wisdom of approving them because such procedures are not within the capabilities of the profession as a whole.

Of the rather definite trends that I have discussed, the trend toward increased operative intervention, with its resultant effect on maternal and infant mortality, alone seems to demand concerted effort in an attempt to change or modify its undesirable features. I can find no record in the literature in which any trend which has existed for more than a hundred years and which shows a constantly increasing acceleration has been checked by the warnings of medical leaders or by similar propaganda. It seems inconceivable to me that any good can come of the present propaganda that is appearing in one of the women's magazines and in certain newspapers, and it appears possible that such articles can actually produce harm. If this is true there can be but one possible solution, i. e., radical changes in obstetric education. The chief adverse criticism of the new obstetrics is on the ground that the profession in general cannot carry out such methods. This is obviously true, for physicians untrained in obstetrics have no place in the new school, just as the physician untrained in surgery should not attempt to do major surgery.

Undergraduate obstetric education is receiving increased attention from the administrative officers of all schools that maintain medical departments, as well as from all of the three leading national societies.

¹⁷ McCord James cited by Skemp A. A. General Practitioner's Response to Challenge of Obstetrics. *Wisconsin M. J.* 31: 527 (Aug) 1932.

The helpful efforts of the Council on Medical Education and Hospitals have been outstanding. Adair,¹⁸ in discussing this subject before the thirty-second Annual Congress on Medical Education in February 1936 summed it up perfectly when he stated "Obstetric teaching of undergraduates requires adequate proportionate time, ample facilities and capable instructors. It is important to carry out this program in all schools as quickly as possible, because even after they are accomplished it will still be ten or fifteen years before the results are generally realized by the public."

Postgraduate obstetric education is, and will continue to be during the next twenty or twenty-five years, the most important factor in molding the new obstetricians. In many hospitals which provide rotating services for interns, a service in obstetrics is not provided for all interns, in spite of the fact that it has been shown that 35 per cent of the average physician's practice during the two years following graduation is in obstetrics. The number of institutions providing adequate residencies in obstetrics is increasing, but the facilities are still too limited. To provide adequate training, I believe in the home delivery service, because it is impossible for the young practitioner to apply what he has learned of the management of labor under the favorable conditions in the hospital to the much less favorable conditions of the patient's own home, unless he has had definite and specific instructions in a specialized technic for the conduct of labor under such conditions and has applied these instructions in a practical way. The training must include a service of not less than six months in obstetric and gynecologic pathology, because without such experience the young obstetrician can never expect to understand the basic processes underlying the conditions which he is attempting to treat. His hospital service can be adequate only if the staff is properly trained and is genuinely interested in teaching.

The recently formed American Board of Obstetrics and Gynecology, whose function it is to supervise, but not to control, obstetric practice to encourage the study of obstetrics and to grant certificates of special knowledge in obstetrics to those who are properly qualified, has already had a pronounced influence in checking radical tendencies, in stabilizing the practice of obstetrics and in setting definite standards which should be met before the practitioner would be justified in claiming that he or she was a "specialist."

The most important phase of postgraduate obstetric education now, and for the next twenty-five years, is the education of the great bulk of practitioners whose undergraduate education may or may not have been inadequate, whose hospital training was often sketchy and who, because of the exigencies of their practice or because of their locations away from medical centers or for other reasons have not been able to keep up with the changes that have occurred during their professional lifetime. There is a very definite duty on the part of all governmental agencies, medical schools, societies and allied agencies interested in maternal welfare to provide systematic instruction for until recently, the forgotten man who is in fact, delivering most of the babies in the United States.

The Children's Bureau, under the Social Security Act, title V part 1 acting with the state health agency,

and always in cooperation with state and local medical groups and organizations, has approved and is fostering extension courses in obstetrics for groups of local practitioners. It is hoped that this phase of each state plan will be as enthusiastically received by the local profession as have similar plans under the auspices of state universities and/or state health departments, in cooperation with the state and local medical societies in California, Florida, Georgia, Iowa, Kansas, Kentucky, Maryland, New York, Oklahoma and Wisconsin.

CONCLUSION

It is a well known fact that the better trained in obstetrics a physician is, the fewer major operative procedures he finds it necessary to perform. While rather drastic changes in the practice of obstetrics have occurred during the present century, I cannot help feeling that obstetrics today is in a transitional stage and that, as obstetric practice gradually comes into the hands of those who have received adequate training many of the present-day trends may be modified and then utilized to make pregnancy safer and easier for the American woman.

PERICARDITIS EPISTENOCARDICA

FRANK BILLINGS LECTURE

GEORGE BLUMER, M.D.

NEW HAVEN, CONN.

To one who for many years enjoyed the privilege of friendship with Frank Billings, and who admired both his character as a man and his acumen as a clinician, it is a source of gratification to be invited to deliver this annual lecture which perpetuates his name. It is natural, I think, in such circumstances, to cast around for some subject in which Frank Billings himself was interested, and among the many topics on which he wrote was pericarditis.¹ For this reason I have chosen to speak today on a particular type of this disease, namely, the so-called pericarditis epistenenocardica.

DEFINITION OF THE TERM

I would remind you, first of all, that it is only in recent years that we have been able to differentiate the angina pectoris of effort from coronary occlusion, and I would point out that, in the past, both conditions were described in the literature of English-speaking physicians as angina pectoris. The term angina pectoris, introduced by William Heberden Sr. in the eighteenth century, has never been generally approved by physicians on the continent of Europe, who have preferred the term stenocardia, first introduced by Brera² in 1813. Their objection to the designation "angina pectoris" lies in the fact that it merely describes a symptom and gives no idea of the pathologic changes underlying the syndrome. On the other hand "stenocardia," derived from two Greek words meaning "narrowing" and "heart," is really no better unless one assumes that by narrowing of the heart continental physicians really mean narrowing of the coronary vessels. In any event it is clear

that pericarditis epistenocardica signifies the type of pericarditis which accompanies the syndrome of stenocardia or angina pectoris

FROM THE HISTORICAL POINT OF VIEW

The historical aspects of pericarditis epistenocardica are not without interest. A survey of the postmortem records of patients who died with a clinical diagnosis of angina pectoris, particularly those who suffered from the so-called status anginosus, clearly shows that pathologists appreciated the significance of coronary occlusion long before clinicians were fully alive to its import. Weigert in 1880 called attention to the relationship between coronary sclerosis, coronary thrombosis and cardiac infarction, and Cohnheim and von Schulthess-Rechberg confirmed his views by their experimental work on dogs. Huber also in 1882 supported Weigert's position and showed that he had a clear insight into the pathology of coronary thrombosis, including its relation to cardiac aneurysm. Furthermore, compilations of autopsies on patients dead of angina pectoris, such as that of Huchard,³ show many with either fresh or organized pericarditis and there are many reports in the literature of small groups or isolated patients with similar pathologic changes.⁴

On the clinical side, the noteworthy historical fact is that pericarditis epistenocardica was undoubtedly described long before its significance was grasped. As early as 1872 Christian Bäumler, then one of the physicians to the German Hospital in Dalston, published in the *Transactions of the Clinical Society of London* a paper entitled "Cases of Partial and General Idiopathic Pericarditis." Three of the patients therein described presented the classic picture of coronary closure with recovery. One of these was Bäumler himself, who had his attack at the early age of 25, the presence of localized pericarditis being observed by his colleagues Denninger and Kussmaul. Bäumler finally died three years ago at the age of 97. Those of his conclusions which are germane to the subject are as follows:

Pericarditis may occur on a very limited part of the pericardial surface. Such partial pericarditis generally passes off in a few days, well marked symptoms being only present for a short time. The chief symptoms of such cases are pain in the precordial region, difficulty in breathing through the pericardial pain, and irradiated pains in the throat, neck, left shoulder and left arm. The heart's action is accelerated, and becomes much more easily affected than in health by even slight muscular action, the temperature of the body is only slightly raised, there is well marked pericardial friction sound, giving evidence of roughness of the membrane, and probably of some fibrinous exudation, but there are no signs of a fluid effusion, of which probably, if any, a very small amount only is present.

When one considers that this description was written before the days of blood pressure estimations and leucocyte counts, it must surely be regarded as an extraordinarily accurate account of coronary occlusion with pericarditis.

Byrom Bramwell⁴ and Pawinski⁵ also reported cases of pericarditis epistenocardica, though they entirely missed their significance. Bramwell surmised that the attack of angina pectoris from which his patient suffered was due to the pericarditis, and the title of

Pawinski's paper, "Concerning the Influence of Dry Pericarditis on the Origin of Stenocardia and Cardiac Asthma," indicates that he held a similar view.

The first writer on pericarditis epistenocardica who fully realized its relationship to coronary occlusion appears to have been Kernig.⁶ In a brief report on the treatment of angina pectoris, which was presented before the Association of Saint Petersburg Physicians in 1892, he stated that "the severe, hours long attacks of angina pectoris are probably caused by thrombotic or embolic processes in the coronary arteries." He calls attention to the pericarditis, which occurs in some cases during the days following the onset of the attack, and explains this as being due to the area of cardiac infarction reaching the pericardial surface. In a later article, published in 1905, he⁷ pointed out how little there was at that time in medical literature about the cardiac changes after an attack of angina pectoris. He contrasted the brief duration of attacks of angina of effort with the so-called status anginosus, called attention to the presence of fever in the latter group of cases, and thought that they also showed enlargement of the heart.

In 1910 Maximilian Sternberg⁸ reported two cases of pericarditis accompanying coronary occlusion and suggested the name "pericarditis epistenocardica." He pointed out that the anginal attack was unusually severe and prolonged, that fever generally appeared on the second day and that a pericardial friction was generally demonstrable on the second, third or fourth day. He stated that the pericardial rub occurred in a circumscribed area and was to be heard only over a period measured by hours. He stated that the fever was not very high and lasted, as a rule, only a few days. He noted that in acute cases there was recent obstruction of a coronary branch with the formation of a necrotic infarct with overlying pericarditis, while in old cases there was evidence of old obstruction in a coronary branch with scar tissue at the site of the former infarct and, not infrequently, cardiac aneurysm. He stressed the noninfectious nature of the pericarditis.

Following Sternberg's paper, numerous references to pericarditis epistenocardica appeared in general reports on the symptomatology of coronary occlusion,⁹ and special papers on this particular sign have been published by Gorham,¹⁰ Adlersberg,¹¹ Loewenberg,¹² Halbron and Lichtwitz¹³ and several others.

It is clear, then, that pericarditis epistenocardica was described as early as 1872 but that its significance has been fully understood only since 1910.

PATHOLOGIC CONSIDERATIONS

A brief consideration of the pathologic changes of pericarditis epistenocardica is necessary in order to understand not only why it is present in some patients but also why it is absent in others. The discussion of the history of the condition has already made it clear that cardiac infarction, resulting from sudden blocking of a branch of one of the coronary arteries, produces localized pericarditis when the necrotic process in the heart wall involves the visceral pericardium. Either the

coronary trunk or its branches may be involved, but most cardiac infarcts are found in the lower third of the anterior surface of the left ventricle in the neighborhood of the apex, because the descending branch of the left coronary artery is most often the site of advanced arteriosclerosis.

A study of autopsies collected by various authors furnishes information as to the frequency and character of the pericardial changes in coronary occlusion. In Huchard's series of 185 postmortem examinations¹⁴ there are thirty-one in which there is clear evidence of recent coronary occlusion and in seven of these, or 37 per cent, acute, usually localized, pericarditis was present. Parkinson and Bedford¹⁴ report eighty-three autopsies on patients dead of coronary occlusion with pericarditis in eleven, or 13 per cent. Wearn¹⁵ found pericarditis in four out of nineteen autopsies, i. e., in 20 per cent. Wolff and White¹⁶ found pericarditis in 48 per cent of their autopsies. A combination of the four series gives 21 per cent with evidence of pericarditis.

These figures show a marked variation in the incidence of pericarditis with cardiac infarct, a result which is, no doubt, partly due to inadequate observation in some of the earlier series, but mainly due to the fact that the number of hearts which were studied is not nearly large enough to furnish a satisfactory basis for statistical evaluation. The important fact that the figures bring out is that the clinician cannot expect to find evidences of pericarditis in every patient with coronary occlusion.

The main reason for the absence of pericarditis in many hearts that are the site of coronary occlusion is doubtless, as Parkinson and Bedford state, the fact that "infarction usually involves the endocardial aspect of the heart and is often separated from the pericardium by a layer of muscle which obtains a blood supply from the epicardial vascular network." As the same writers observe, another factor which may prevent spread of the lesion to the pericardial surface is adiposis of the visceral layer.

While these anatomic facts explain the infrequency with which the clinician detects pericardial friction in his patients with coronary occlusion, they do not tell the whole story. Sometimes a friction rub is absent because a patient has had a previous attack which has led to obliteration of the pericardial sac. More frequently the failure to detect pericarditis is due to the brief duration of the friction rub, which may be present for only a few hours. Nor should it be forgotten that even widespread pericarditis is frequently overlooked by the clinician. Some patients, of course, do not live long enough for signs of pericarditis to develop.

The type of exudate is usually described as fibrinous, and it is only in occasional patients that effusion, sufficient in amount to be detected clinically, is present. Several observers note that the exudate is free from bacteria.

CLINICAL FEATURES

It is difficult to judge of the frequency with which pericarditis may be recognized by the clinician in patients with coronary occlusion. Parkinson and Bedford recognized it only seven times in a hundred patients, but there are many reports on small groups of patients in whom it was discovered much more fre-

quently than this. In 109 patients whom I saw at some period during the ten days immediately following an acute coronary occlusion, thirty-two, or 22 per cent, showed pericarditis. As many of these patients were seen but once it would seem as though this was a conservative figure, but when one considers that a consultant is apt to see the more serious cases it may be too high. The clinical reports, like the pathologic reports, do not, as yet, cover a number of cases sufficiently large for statistical purposes.

The day of the disease on which pericarditis is first likely to be noticed is obviously of diagnostic importance. In none of my thirty-two positive cases was pericarditis originally detected after the tenth day. In twenty-nine of the thirty-two positive cases it occurred on the first to the fourth day. In the remaining three patients it was noted on the fifth, the eighth and the tenth day. In only three patients was pericarditis recognized within twenty-four hours of the onset of the attack, so that in 81 per cent of the positive cases it occurred on the second, third or fourth days, twelve times on the second day, eight times on the third day, and six times on the fourth day. The cases reported in the literature show approximately the same distribution.

The location of the friction rub was, as might be expected from the pathology of the condition, most frequently in the region of the lower portion of the left ventricle. In five patients the pericardial rub was heard in the apical region, usually to the median side, in twelve it was described as being over the lower end of the sternum, usually on both sides of the median line but occasionally to the right or the left of it. In only three patients was the friction rub limited to the basal region.

The extent of the friction rub was almost always limited. Usually it was heard over an area not more than 5 or 6 cm in diameter. In a few patients the area of friction enlarged somewhat as the disease progressed, and in one patient, with only a small area involved, the sound of the friction was transmitted to both axillae and to the back. There was one patient in whom the friction was heard all over the left side of the heart and one in whom, at its period of maximum intensity, it was audible from nipple to nipple and from the episternal notch to the xiphoid cartilage.

The duration of the friction rub was usually transitory, as is generally stated by other observers. In patients seen on successive days a loud friction rub often disappeared between the first and the second examination. However, there was one patient in whom the friction persisted for four days, one in whom it lasted five days, three in whom it was present for eight days, and one who showed friction continuously for two weeks.

No patients with demonstrable pericardial effusion were observed by me, but such cases occur at times and have been described by Master and Jaffe¹⁷ and by others.

It is not possible to state definitely whether pericarditis accompanying coronary occlusion has any bearing on the prognosis of the disease. Of my thirty-two patients with pericarditis episthenocardica, thirteen died and nineteen recovered. This would seem to indicate that the presence of pericarditis is not necessarily of evil omen, but the number of cases reported is altogether too small to permit of positive conclusions.

¹⁴ Parkinson J. and Bedford D. E. *Lancet* 1: 4 (Jan 7) 1928.

¹⁷ Master, A. M. and Jaffe H. L. *Coronary Artery Thrombosis with Pericardial Effusion* J. A. M. A. 104: 1212 (April 6) 1935.

My experience does not permit me to pass judgment on the claim of Barnes¹⁸ that a characteristic electrocardiographic pattern is found in patients with coronary occlusion and pericarditis. Barnes describes the typical electrocardiographic record in such patients as showing elevation or upward rounding of the RST segment in all leads and states that this may be followed by inversion of the T wave in all leads.

CONCLUSIONS

1 A usually localized and usually transitory pericarditis is clinically demonstrable in a certain proportion of patients with coronary occlusion, possibly in a third of them.

2 Occasionally much more widespread pericarditis is present, which may involve the entire pericardial sac and eventually lead to its obliteration.

3 In some patients the signs of pericarditis persist for as long as two weeks.

4 When present in a patient suspected of having coronary occlusion, a localized pericarditis is of great diagnostic value, its prognostic value cannot be determined until a large series of cases is available for analysis.

195 Church Street

WOUNDS OF THE THORACIC VISCERA

DANIEL C. ELKIN, M.D.

ATLANTA, GA.

The danger from chest wounds is in a large measure due to the narrow margin of safety under which the thoracic viscera work. A rapid change of pressure relationships within the thorax affects the aeration of the blood, the filling and emptying of the heart, and the circulation not only in the thorax but also of the whole body. A knowledge of certain fundamentals of the mechanics of respiration is therefore a necessary prerequisite for the surgery of this field.

Wounds of the thorax are common in civil practice as well as in war surgery. In the past five years (1931 to 1935 inclusive) 553 patients have been treated at the Emory University Division (colored) of the Grady Hospital (municipal) for penetrating chest wounds. That the number of such cases is increasing is shown by the fact that, in the nine years previous to 1931, 511 similar cases were treated in the same hospital.

Thoracic injuries in civil life are different from those seen in war injuries and are less severe. In the former a knife, ice pick, or pistol bullet are the usual weapons, and large sucking wounds, such as are made by shrapnel, are less frequently seen. The lodgment of clothes, ribs and shell, giving rise to serious infection, is therefore more rarely a complicating factor.

The most common weapon is the "switch blade" knife (354 cases), with a long, thin, 4 inch blade. It usually causes a small external opening, which immediately closes, occasionally when pulled out in an intercostal space it produces a large sucking wound. Next to the knife, the ice pick (ninety-three cases) is the weapon most commonly used. It rarely produces a sucking

wound and the injury produced by it is not severe unless the heart is penetrated, which happened once in this series. Of decreasing frequency are the pistol (eighty-four cases) and shotgun wounds (eighteen cases), accidental injuries from nails and splinters, and crushing injuries from automobile accidents.

Pleuropulmonary lesions may be divided into those having (1) open wounds of the thoracic wall and (2) those having closed wounds. Open wounds are by far the more dangerous, the degree of danger depending on the size of the wound, the amount of foreign material carried into the chest, and the injury to the viscera. If the opening is smaller than the larynx, the lung collapses, but on inspiration partial expansion occurs and respiration is only slightly embarrassed. If the opening is larger than the larynx, air will enter more freely than through the trachea and mediastinal flutter will occur. This subjects the heart and great vessels to varying degrees of pressure, and some air passes from one lung to the other in useless exchange. The clinical picture is one of terror, air hunger, and eventual asphyxiation. The first principle in the treatment of any sucking wound is the immediate closure of the opening. In this series forty patients had sucking wounds and were so treated.

Pleuropulmonary lesions with a closed wound are more common and far less dangerous. They are usually caused by a knife or ice pick, and the external wound has closed spontaneously or has been converted into a closed lesion by suture. The main problem in the treatment of thoracic injuries in civil life is therefore concerned largely with closed wounds and the conditions arising from injury to the thoracic viscera. In this series treatment was always dependent on the symptoms exhibited by the individual patient rather than by a set rule. In the main the treatment was conservative and nonoperative, although operation was carried out for heart wounds, for large lacerated wounds of the lung, for hemorrhage from an intercostal or internal mammary vessel, or for compression pneumothorax.

The most frequent conditions encountered were hemothorax, pneumothorax, hemopneumothorax and subcutaneous emphysema. The general symptoms of dyspnea, painful respiration and hemoptysis were the most common.

HEMOTHORAX

Hemothorax occurred in 209, or 37 per cent of the patients, and varied from a small amount of blood as disclosed by roentgenogram to an amount filling one pleural cavity. Its source is from a wound in the lung, the heart, or an internal mammary or intercostal vessel. When there is evidence of a rapidly increasing hemorrhage or of a heart wound, immediate operation should be carried out, but as a rule wounds of the lung will stop bleeding as the lung is compressed. Many methods of treating hemothorax have been advocated, and until the past three years the method in this service has consisted of bed rest, morphine for relief of pain, and frequent aspiration of any bloody fluid. Having shown by animal experiments¹ that blood and clots were rapidly and completely absorbed with few pleural adhesions, we began less frequent aspiration in the human cases. The results in the past three years seem to justify the present plan of treatment, namely, aspiration only for pain and dyspnea. In those patients requiring aspiration the average amount removed was

18 Barnes A. R. *Am Heart J* 9: 734 (Aug.) 1934.
From the Department of Surgery, Emory University School of Medicine.

Read before the Section on Surgery, General and Abdominal at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1936.

1 Sandison J. C., and Elkin D. C. *Penetrating Wounds of the Chest*. *J Thoracic Surg* 2: 453 (June) 1933.

600 cc. In one case 1,400 cc. was removed on the first day, 1,400 cc. on the second day and 3,400 cc. on the fourth day. This patient recovered and was discharged from the hospital on the eleventh day. The amount of fluid removed from the chest was as great in stab wounds as in those caused by bullets.

The mortality for patients with hemothorax treated by conservative methods was 6 per cent. The deaths were as frequent in stab wounds as in those produced by bullets. Patients with hemothorax usually have an elevation of temperature for several days, if this continues for a week, aspiration for culture should be done.

PNEUMOTHORAX

Pneumothorax occurred in 133, or 24 per cent, of these cases. This condition, unless associated with some other injury, rarely required treatment other than rest and morphine. The presence of air, collapsing and splinting the lung, in itself aids healing, and as the air is absorbed the lung readily reexpands. Lung expanding exercises, as with blow bottles, can do no possible good in closed pneumothorax and may cause harm. If dyspnea is distressing, the aspiration of a portion of the air will give great relief but should be done with great care lest the wound in the expanding lung be reopened. Bilateral pneumothorax may be produced by a wound of both lungs, as occurred twice in this series, or by sudden compression of the chest without an external wound. The latter was seen on one occasion as a result of an automobile accident in which the patient was thrown suddenly against the steering wheel, probably rupturing both lungs without a penetrating wound. If dyspnea is marked, bilateral aspiration or water-seal drainage of both lungs should be done.

Compression pneumothorax, caused by a valvelike action of a wound in the lung or bronchus, requires immediate treatment. The symptoms are those of rapidly increasing air hunger and cyanosis, with displacement of the mediastinum toward the uninjured lung. With each inspiration air enters the pleural cavity but cannot escape on expiration. Thus the intrathoracic pressure is gradually increased, compressing the venae cavae and interfering with the circulation. Treatment consists of removal of the air by suction or by the introduction of a water-sealed intercostal tube of sufficient size to allow its escape.

HEMOPNEUMOTHORAX

Hemopneumothorax occurred in 200, or 36 per cent, of the cases. In general the symptoms are similar to those in which hemothorax or pneumothorax was present and the treatment was essentially the same. As in hemothorax and pneumothorax, the mortality was the same (approximately 6 per cent).

SUBCUTANEOUS EMPHYSEMA

Subcutaneous emphysema occurred in 40 per cent of the cases. As a rule the area was small and rapidly absorbed and it required no special treatment. Occasionally the subcutaneous air spreads over the whole body and may cause pressure on the trachea and interfere with breathing. In one instance an ice pick wound at the angle of the scapula produced such a lesion. It was successfully treated by introducing a needle into the pleural cavity and aspirating the air by suction. Such lesions are probably caused by a laceration of the lung or bronchus, which produces a valvelike wound and allows air to escape into the subcutaneous tissues with

each inspiration. Mediastinal emphysema occurs when pleural air escapes directly into the mediastinum and spreads upward into the neck and over the body. This condition is dangerous because of pressure on the trachea and should be treated by incisions in the supra-sternal space. It occurred in one instance in this series, on the twelfth day after operation for a stab wound of the heart. Aspiration of the air from the pleura was attempted, but the patient died two days later from tracheal compression.

INJURY OF THE HEART

Crushing injuries of the chest are frequently seen as a result of automobile accidents. Many are immediately fatal and are due to rupture of the heart, lungs or great vessels as a result of compression, or penetration of the viscera by sternum or broken ribs. Little attention has been paid to nonpenetrating heart lesions which are not fatal. Three instances have been previously reported by me² and it probably occurs more frequently than is supposed. Certainly there is no reason to believe that the heart, situated as it is between the sternum and the spine, is not subject to contusions of considerable severity and from which recovery takes place in the majority of instances. The most common cause of such an injury is one in which the driver is suddenly thrown forward against the steering wheel, and the sudden compression may injure the heart without fracturing the sternum or ribs. Any patient who is struck in the chest should be suspected of such an injury, particularly if symptoms of precordial pain, dyspnea and tachycardia are present. Persistence of these symptoms, together with irregularity of the heart, cyanosis and a peculiar "tick-tick" quality of heart sounds, makes the diagnosis almost certain. The treatment is entirely symptomatic. The chief reliance is to be placed on morphine and sedatives for rest, and on oxygen for dyspnea and cyanosis. The patient should be confined to bed until all symptoms have subsided.

Eleven patients, or 2 per cent, in this series had stab wounds of the heart and were treated by operation. All except one survived the operation, and six recovered. Five died from pneumonia or pericarditis, and one from mediastinal emphysema on the fourteenth day. The diagnosis of a wound of the heart is not difficult if the injury is suspected, as it should be in all lacerations of the chest. There is usually a history of freedom from any symptoms for several minutes, this is followed by collapse. External bleeding is profuse at first, but, with the stage of collapse, is checked. Both the collapse and the stopping of the hemorrhage are due to tamponade of the heart. The pulse is weak or absent, and the arterial pressure low or unobtainable. The venous pressure is raised, as may be determined by the manometer and as is evidenced by prominent struted external jugular veins. Fluoroscopic examination is of aid, since in tamponade there is practically no cardiac movement.

INFECTION

Contrary to general opinion, infection of the pleura and of the thoracic viscera rarely follows penetrating wounds. Infection of the pleura in the form of empyema or infected hemothorax occurred in eight instances, or 1.4 per cent, of all cases. Knife and bullet wounds were equally responsible. Five followed hemothorax and three followed hemopneumothorax. Seven

² Elkin, D. C. Traumatic Lesions of the Thorax, South. M. J. 28:4 (Jan.) 1935.

of the eight patients recovered after rib resection and open drainage. One patient with bilateral chest wounds, produced with an ice pick, developed an abscess of the lung, which healed spontaneously. Ten patients died of bronchopneumonia, which was attributed to direct lung injury, although this complication occurs with such frequency after any operation that not all deaths can be said to be due to trauma, but they were so considered in estimating the mortality percentage.

CAUSE OF DEATH

Thirty-three patients or 6 per cent died as a direct result of thoracic injury or of complications resulting from the injury. The most common cause was shock and hemorrhage, which occurred in eighteen instances. Next in frequency was pneumonia (ten cases), infection (four cases) and mediastinal emphysema (one case). Of the four patients with infection two died of pericarditis following operations on the heart, one of empyema and one of bacteremia.

Twenty-six patients with multiple injuries apparently died from causes other than those resulting from thoracic trauma and are not included in the mortality percentage. These included eighteen cases of peritonitis or hemorrhage from the abdominal viscera, two patients with hemiplegia from spinal cord wounds, three with massive hemorrhage from the neck or extremities, and one with a gunshot wound of the brain.

COMMENT

In this series of 553 cases of thoracic wounds, treatment was attempted by conservative methods. Except in wounds of the heart, operative procedures have been rarely carried out. Aspiration of blood or air has been practiced only in those patients having pain and dyspnea. With these methods the mortality was 6 per cent. One hundred and forty-eight patients were in shock and most of them had hemothorax or pneumothorax on entrance to the hospital. Treatment of this class of patient presented the most difficult problem and eighteen of them died, usually within the first twenty-four hours after admission, without reacting from shock. Some of that number might have been saved by operation. This would have necessitated open thoracotomy and lung suture. Had this method been carried out on a large number of patients, it is doubtful whether the mortality would have been as low as 6 per cent. Thoracotomy with exteriorization and extrapleurization of the lacerated lung has been advocated and practiced by Connors and Stenbuck.³ By this procedure they have unquestionably saved a number of lives, but their mortality in a small series of thirty-two cases was 12.5 per cent.

478 Peachtree Street

ABSTRACT OF DISCUSSION

DR. FREDERICK CHRISTOPHER, Evanston Ill. Dr. Elkin's results have not to my knowledge been equaled. In a series of 553 cases treated by conservative methods the mortality has been only 6 per cent. Efforts to reduce this exceptionally low mortality will be centered on a study of indications for operative intervention. Dr. Elkin has employed surgical treatment in (a) the open sucking wounds, (b) compression or tension pneumothorax, (c) widespread subcutaneous emphysema with tracheal pressure, (d) mediastinal emphysema (e) stab wounds of the heart, (f) large lacerated wounds of the lung (g) severe hemorrhage from intercostal vessels, and (h) residual empyemas. In hemothorax only aspiration is employed for the relief of

pain and dyspnea. When there is a possibility of a traumatic diaphragmatic hernia, elective intervention should be carried out later if the symptoms do not demand immediate operation. Bettman states that, in cases which are not immediately fatal, hemorrhage usually occurs from a bleeding intercostal artery. When this bleeding threatens to be serious, Bettman does a thoracotomy and checks the bleeding by a ligature which encircles the rib, thus compressing the vessel. Increasing hemorrhage may also come from a laceration of the lung. In traumatic hemothorax the advice of Foster and Prey is of interest. These workers contend that they have reduced the hospital stay 50 per cent by aspiration followed by artificial pneumothorax. Hedblom called attention to the fact that a traumatic empyema is of more serious import from the standpoint of both prognosis and treatment than the ordinary postpneumonic type. He said that complicating a pneumothorax with complete collapse of the lung results in infection involving the whole pleural cavity, thus rendering toxic absorption correspondingly greater. Contusion of the heart has been carefully studied by Beck, who called attention to the value of electrocardiograms in the diagnosis. The occurrence of ileus as a complication of rib fracture has been mentioned by Bettman and by myself. The autotransfusion of the patient's blood in heart wounds, as suggested by the Watsons, should be a valuable addition to the operative treatment. These authors stated in a paper published in *THE JOURNAL* that they removed the fluid blood from the pleural cavity by means of laparotomy pads, which they wrung out in 2 per cent solution of sodium citrate, and injected the blood into the patient by the intravenous method. Perhaps in no other injury is there the need for alert watchfulness that there is in thoracic injuries. Not only must there be careful observation, but a definite plan must be well in hand for taking care of the urgent sequelae. The man in general surgical practice will do well to keep in mind (a) the need of immediate closure of sucking wounds, (b) the ease of aspirating air from a tension pneumothorax when there is not excessive bleeding, and (c) that thoracotomy can be readily carried out with the ordinary modern gas machine and an intelligent anesthetist.

DR. L. WALLACE FRANK, Louisville, Ky. The primary treatment of pleuropulmonary wounds resolves itself into the treatment of hemorrhage or the closure of sucking wounds of the chest wall and the relief of tension pneumothorax. Fortunately, the latter two conditions are infrequent, otherwise the mortality would be much higher. Most sucking wounds are larger than the opening of the larynx and trachea and hence immediate total collapse of the lung occurs and not infrequently mediastinal flutter with resultant marked circulatory distress. Such wounds must be closed at the earliest possible moment. Occasionally one observes a small oblique wound of the chest wall through which, as a result of a valvelike action, air is sucked into the pleural space with each inspiratory effort and at expiration the wound becomes closed. The pressure within the thorax mounts rapidly, the heart and mediastinal structures become displaced, circulatory and respiratory embarrassment soon become evident, and death rapidly supervenes unless the air is removed. In such cases the insertion of a moderate sized aspiration needle into the chest may be life saving. The treatment of hemorrhage in cases of pleuropulmonary injuries is seldom necessary. In hemorrhage from intercostal or internal mammary arteries, operative intervention is required. In many cases, a watchful waiting policy may be pursued. Should symptoms of marked intrathoracic pressure develop, some of the fluid may be aspirated. As a rule the increasing pressure stops the hemorrhage, this is particularly true when the bleeding comes from injury to the lung. Here conservative treatment may be followed. In such cases, however, frequent blood counts should be made and transfusion employed when indicated. At the end of ten days or two weeks, if the quantity of blood within the chest is large, as determined by x-ray studies, I remove the fluid by aspiration. I have seen empyema occur in cases of hemothorax as late as six months after the injury. Operative procedures for this condition may be prevented by early aspiration. When the hemothorax is small I prefer to wait for the possible absorption of the fluid. Should this not occur after a reasonable length of time, I remove the bloody fluid by aspiration. During the past two years, thirteen patients

³ Connors, J. F. and Stenbuck, J. B. Penetrating Stab Wounds and Bullet Wounds of the Chest. *Ann. Surg.* 97: 258 (April) 1933.

with heart wounds were admitted to the Louisville City Hospital and ten of the cases were diagnosed. Eight patients were operated on and five lived. Two patients treated conservatively likewise made a satisfactory recovery. The indications for operative intervention in cardiac wounds are bleeding or cardiac tamponade. Before the Southern Medical Association last November, Bigger discussed heart wounds and emphasized an important point in the diagnosis of cardiac tamponade, namely, the absence of cardiac movement when the patient is studied fluoroscopically, this could probably best be demonstrated by roentgenkymography. This is more important than the size of the cardiac shadow. Tamponade is treated by pericardiectomy with the evacuation of the blood and suture of the wound, followed by closure of the incision without drainage.

TUMORS OF THE SPINAL CORD AND THEIR RELATION TO MEDICINE AND SURGERY

WINCHELL McK. CRAIG, M.D.
ROCHESTER, MINN

Diseases of the central nervous system no longer carry the discouraging prognosis with which they formerly were associated. The two important factors responsible for this are the identification of certain lesions of the central nervous system with constitutional disorders, and the development of neurologic surgery.

The recognition of the neurologic aspects of certain systemic diseases and infections has been followed by a more specific type of therapy, which has proved both preventive and curative.

The advances that have been made in the treatment of syphilis, neurosyphilis, and the various infections that involve the central system, either primarily or secondarily have increased the therapeutic armamentarium of the neurologist. A clearer conception of the toxemias and their neurologic phases, pernicious anemia and its treatment, diabetes, and other glandular dysfunctions has clarified many problems in neurologic therapy.

The first successful removal of a tumor of the spinal cord, by Horsley¹ opened a new field of therapy for neurologic disorders that affect the spinal cord and exerted a profound influence on neurology, and on medicine in general. Following Gowers' diagnosis and Horsley's operation, a captain of the British army was transformed from a long suffering, helpless individual to an active person free from disability and pain. Following this epochal operation two facts were impressed on the medical profession: first, that operable tumors really do exist and can be found, if looked for; second, that the early surgical removal of these tumors is followed by relief of paralysis, numbness and pain.

Tumors of the spinal cord are not rare, and as the years have passed since the first one was removed the number of these tumors that have been diagnosed and removed has increased. Similar to other pathologic conditions the number of these tumors is increasing, not because the tumors are more prevalent than they were formerly, but because they are being recognized earlier and are being removed before the prognosis is hopeless.

The symptoms of tumors of the spinal cord are extremely interesting, while they may conform to a

definite pattern, their protean manifestations make them an important factor in general diagnosis. Intraspinal tumors may masquerade for many years as syphilis, pernicious anemia, multiple sclerosis, syringomyelia, sciatica, arthritis, myositis or neuritis. These tumors may produce pain that is referred to the abdomen, pelvis and extremities. They may simulate appendicitis, cholecystitis, the twisted pedicle of an ovarian cyst, and fibromyomas, and they may produce such deformities as scoliosis, spasticity and paralysis.

Oppenheim² has described the symptoms of tumors of the spinal cord in a general way and has divided the clinical course into three stages. The first and longest stage is characterized by pain, which also is the earliest and most common symptom. In more than 300 cases in which the diagnosis of tumor of the spinal cord was proved at the Mayo Clinic, pain was present in approximately 80 per cent. The average duration of this symptom was considerably more than two years. The pain may be in the spinal column, at the site of the tumor. It may be referred to the lower extremities, even in cases in which the tumor is situated high in the spinal canal, but it usually is referred along the distribution of the posterior root of the spinal nerves and is known as "root" pain. It is the peripheral extension of root pain and its various qualities, such as aching, squeezing and piercing, that so frequently suggest disease of the pericardium, pleura, biliary, urinary, and gastro-intestinal tracts, peripheral nerves, muscles or bones. If pain is the first symptom, there may be an interval before any sensory or motor changes take place. This aids in making the diagnosis. One of the most important characteristics of the pain is that it may be worse on coughing or sneezing, it usually becomes worse at night, and the patient often will arise at an early hour in the morning and sleep in a chair.

The second stage in the development of the symptoms of tumors of the spinal cord has to do with the changes in motion and sensation. Numbness or peculiar sensory feelings may call the patient's attention to the sensory changes. This may be the initial symptom or may follow the pain. Sensory changes usually go hand in hand with motor changes. The classic Brown-Sequard syndrome may be present. This consists of diminution of power on one side of the body and sensory changes on the other. As the compression of the spinal cord persists and increases, the third or final stage develops. This consists of complete paralysis.

DIFFICULTIES OF DIAGNOSIS

In reviewing the records of patients who have been relieved of disabling symptoms by surgical removal of tumors of the spinal cord, at the clinic, it was extremely interesting to note the many problems that involved general medicine and surgery and continually presented themselves during the development of the symptoms and before a correct diagnosis could be made.

One of the most important considerations is that the lesion may be associated with a constitutional disorder, and for this reason a complete examination should be made. This, of course, should include the usual examination of the blood and urine, and the Wassermann reaction of the blood, and other serologic tests, if they are indicated. Roentgenograms have been of value in localizing tumors of the spinal cord in about 60 per cent of the cases, and for this reason good roentgenograms

From the Section on Neurologic Surgery, the Mayo Clinic.

of the spinal column and thorax should be made. A complete neurologic examination is necessary for some small and apparently insignificant change in motor, sensory or reflex power may be of extreme importance in making a differential diagnosis. The examination of the cerebrospinal fluid is imperative, for not only are the physical characteristics important but the chemical and serologic changes may be the one clue to the correct diagnosis. Increase in the amount of protein, increase in the number of cells, a yellow color, changes in pressure and response to changes of intracranial pressure especially to compression of the jugular veins, should all be noted.

The examination of the cerebrospinal fluid is especially important whenever there is a question of syphilis, as there so frequently is in the majority of cases. I have been impressed by the number of cases in which a diagnosis of syphilis had been made and treatment started without conclusive evidence of the presence of this disease. Even in the face of a positive Wassermann reaction on the blood, the underlying cause of the symptoms sometimes may be a tumor of the spinal cord. The following case illustrates some of the diagnostic difficulties.

A man who came to the clinic had had slight stiffness in his legs for twenty years. Three years previously he had begun to drag his left leg and three months later the right leg had become involved. About the same time he had begun to have cutting pains across the lower part of the abdomen, which had come on suddenly, had remained for about half an hour, and then had disappeared. His clumsiness and inability to walk had become so severe that, within a year, it had become necessary for him to use a wheelchair. This condition had continued until he came to the clinic. He also had had some difficulty in emptying his bladder.

The Wassermann reaction of the blood was strongly positive, and the reaction of the spinal fluid was negative. Roentgenologic examination of the spinal column did not reveal any abnormality. Neurologic examination revealed an almost complete paralysis of the lower extremities, with a loss of pain, temperature and tactile sensation below the level of the tenth thoracic segment. There was a complete loss of vibration and joint sensibility of the lower extremities. The lower extremities were found to be very spastic. During spinal puncture it was noted that the column of fluid in the manometer did not change position when the jugular veins were compressed, this denoted complete subarachnoid block. The progressive paralysis of the lower extremities, which had been present for two years and which had been associated with girdle pains, and the subarachnoid block had suggested a lesion of the spinal cord which had been diagnosed and treated as syphilis because of the positive Wassermann reaction of the blood and in spite of the negative reaction of the cerebrospinal fluid.

A large extradural hemangioma was removed through a laminectomy, which consisted of the removal of the spines and laminae of the sixth, seventh eighth and ninth thoracic vertebrae. The tumor measured about 4 cm in length, 2 cm in width and 1 cm in thickness. The patient made an uneventful convalescence and returned home without much improvement, except in vesical control. Two years later he returned to the clinic, at that time he was walking with only a slight amount of spasticity of the lower extremities and the Wassermann reaction on the blood was only slightly positive.

The striking features in this case were the onset of motor and sensory changes, which appeared before the pain, the positive Wassermann reaction of the blood, which indicated syphilitic infection, the negative Wassermann reaction of the cerebrospinal fluid, which made the diagnosis of syphilis questionable, and the marked improvement in all symptoms following removal of the tumor.

SYMPTOMS OF PERNICIOUS ANEMIA

Pernicious anemia is seldom confused with tumors of the spinal cord, however, Woltman³ found that in approximately 127 per cent of cases of pernicious anemia that were seen at the clinic the patients came to the clinic for the express purpose of seeking relief from symptoms directly attributable to involvement of the nervous system. Chief among these symptoms were paresthesias, especially numbness and tingling of the hands and feet, which were present in about 80 per cent of all the cases of pernicious anemia, regardless of whether or not involvement of the nervous system could be demonstrated objectively. Occasionally a patient complained of a girdle pain (28 per cent) or the sensation of a tight band around the knees (17 per cent). A number of patients presented themselves for examination because of inability to control the arms and legs properly. Cramping of the calves occasionally proved to be the source of great discomfort. A patient may die of pernicious anemia without ever presenting any evidence of involvement of the central nervous system. On the other hand, the appearance of nervous symptoms may precede the onset of the anemia, this was true in 14 per cent of the cases seen at the clinic. The symptoms that preceded the anemia usually were paresthesias. The following case demonstrates how a tumor of the spinal cord may be mistaken for pernicious anemia.

A woman, aged 47, came to the clinic complaining of numbness and tingling in the toes, which gradually had extended to the legs and up to the thighs and had been getting progressively worse for two years. When the numbness first appeared she had been examined by her family physician, who found that she had a relative anemia and who made a diagnosis of pernicious anemia. He had administered hydrochloric acid and liver extract, which had improved the condition. In view of the fact that the condition had been diagnosed as pernicious anemia, with involvement of the central nervous system, a poor prognosis was given, and the patient and her husband had accepted this diagnosis and had become resigned to what seemed the inevitable outcome. However, as time progressed and the general condition of the patient had improved without any change in the numbness, the physician referred her to the clinic for diagnosis. A more detailed history revealed that about two months after the onset of the numbness and tingling she had noticed some difficulty in walking in the dark, and as the condition had progressed she had been unable to feel the floor with her feet. Occasionally she had fallen down. The legs gradually had become stiff, and she had noticed that she could not walk as fast or move as quickly. The patient's condition had become steadily worse during the previous four months, and at the time of her examination she was afraid to go out alone. She never had had any pain or incontinence of urine or feces.

Examination of her blood revealed that the value for the hemoglobin was 89 per cent and that there were 4,290,000 erythrocytes and 7,500 leukocytes in each cubic millimeter of blood. The gastric acidity was within normal limits. The roentgenologic examination of the thoracolumbar portion of the spinal column revealed slight thinning and flattening of the pedicles of the sixth and seventh thoracic vertebrae, on the left side. The rest of the general examination did not reveal any abnormality.

Neurologic examination revealed almost complete loss of pain tactile and temperature sensation up to the level of the eighth thoracic segment. There was a loss of vibration and joint sense in the lower extremities. There was mild loss of strength in the lower extremities and there was some spasticity. Ankle clonus was found bilaterally, but there was a loss of epigastric, midabdominal and hypogastric reflexes. Chaddock's and Rossolimo's reflexes were present on both sides. Examination

³ Woltman H. W. The Nervous Symptoms in Pernicious Anemia. *Minnesota Med* 2: 306-310 (Aug.) 1919.

of the spinal fluid revealed 160 mg of total protein per hundred cubic centimeters of spinal fluid, a positive globulin test, and 3 small lymphocytes per cubic millimeter of spinal fluid. There was a definite delay in the rise and fall of the fluid in the manometer following compression of the jugular veins. Because of the anesthetic level, the roentgenologic changes and the partial subarachnoid block, a diagnosis of tumor of the spinal cord was made. Operation revealed a large meningioma, which measured 25 by 15 by 15 cm., situated opposite the sixth thoracic segment. The tumor was removed completely, with its base. Following the operation the patient had an uneventful convalescence, and at the time of her dismissal from the clinic there was marked improvement in her sensation and a lessening of the spasticity. A letter received from the patient six months after she had returned home revealed a loss of all disability and complete return of normal sensation and function of the lower extremities. When she was examined two years later there was no evidence of any previous trouble.

There is no physiologic reason why certain constitutional diseases cannot occur simultaneously with the development of the symptoms of a tumor of the spinal cord, but the foregoing case has been presented to show how difficult a differential diagnosis can be when the symptoms of the tumor are so atypical that they simulate the neurologic manifestations of another disease.

PRESENCE OF TUBERCULOSIS

Tuberculosis of the central nervous system usually is preceded by a demonstrable focus in some other part of the body, or, if it involves the spinal cord, there usually are associated bony changes which are demonstrable in the roentgenograms. Further, if the tuberculous lesions are within the meninges or involve the nervous tissue, the prognosis is very bad. However, tuberculomas of the spinal cord may be present without any evident focus elsewhere in the body. They may be removed surgically and all symptoms may be relieved when they are extradural and the dura remains intact during the removal. The following case emphasizes the justification of operation following a rapid course, and in the face of a poor prognosis. Further, it proves that tuberculosis encountered early in the operation should not deter an attempt to remove all granulomatous tissue, and the fact that the patient was well six years after operation indicates that a cure had been effected.

A youth, aged 19 years, came to the clinic complaining of paralysis of the lower extremities. He had had pneumonia two years previously, and after recovery he had been perfectly well until six months previous to his registration at the clinic, when he had influenza associated with a cough and pains in the thorax, and some elevation of temperature. He had recovered in about a month and had been perfectly well until four weeks previous to his registration at the clinic, when a dull pain had developed in the upper part of his thorax and back. This had been associated with a dry cough, which had increased the pain. Two weeks later, after the pains in the thorax had decreased, he had noticed numbness in his legs which had extended up to his knees. This had been very slight at first but gradually had become worse and in three days it had extended to his hips. With the subjective numbness he had lost all sensation and all ability to move his legs, this loss of function had become complete in four days. In one week following the onset of his symptoms he had become completely paralyzed below the waist, the paralysis had been associated with a complete anesthesia. Some difficulty in voiding also had developed. Roentgenologic examination of the thorax showed some small localized infiltrations which were thought to be the result of localized bronchiectasis. Examination of the thoracic vertebrae did not disclose any abnormality. Neurologic examination revealed a complete paralysis of the muscles below the level of the eighth and ninth thoracic segments and a complete loss of sensation vibration and joint sensibility below the sixth and seventh thoracic segments. The cerebrospinal fluid proved to be yellow and it coagulated immediately. There was no

response to jugular compression. A diagnosis of transverse myelitis was made, and because of the age of the patient and the sudden onset a laminectomy was advised, in spite of a very poor prognosis. In the course of the operation an inflammatory lesion of the muscles was encountered, microscopic examination revealed that this lesion was tuberculous. The epidural space was found to be filled with a granulomatous mass, which seemed to encircle the spinal cord, although the largest portion was compressing the cord from the posterior aspect. The entire inflammatory mass was removed, and the wound was closed. The patient had an uneventful convalescence. The wound healed by primary intention, but there was little or no return of function of the lower extremities, although the function of the sphincters had improved definitely. The patient returned home and remained in a wheelchair for six months, at this time he was able to be up and about on crutches. At the end of a year he was able to walk without any difficulty. He returned to the clinic for reexamination six years later, in 1936, at which time he was perfectly well. Roentgenologic examination of the spinal column did not reveal any further involvement with tuberculosis, and he had made a splendid recovery.

MALIGNANT TUMORS

The foregoing case and the next case have a short history in common, and yet they are so different that they illustrate many points in contrast. The rapid development of symptoms of tumors of the spinal cord always raises the question of malignancy and, surprisingly enough, both primary and secondary malignant tumors of the spinal cord occur so infrequently that, even in the presence of malignant changes elsewhere in the body, experience has shown that surgical exposure of the tumor to make a differential diagnosis is justified. In the following case, the diagnosis of syphilis also had been made on account of a positive Wassermann reaction of the blood, and there had been a questionable diagnosis of metastasis of carcinoma of the breast, which had been removed four years previously. To confuse the diagnosis further, the patient responded temporarily to antisyphilitic treatment, which is difficult to explain in the light of the tumor that was found at operation.

A woman, aged 55, came to the clinic complaining of coldness of the lower extremities, loss of sensation, difficulty in voiding, and shooting pains in the thorax. She had undergone a radical mastectomy four years previously for carcinoma of the breast. Three months before her registration at the clinic she had noticed a numbness and dead feeling in both feet. Two or three weeks before she was examined, she had had difficulty in voiding. A roentgenogram of the spinal column did not reveal any abnormality. The Wassermann reaction of the blood was markedly positive, but that of the spinal fluid was negative. The neurologic examination revealed a weakness of the lower abdominal muscles and the muscles of the lower extremities, a decreased sensibility to pain and temperature over the lower extremities, and a decrease in joint and vibration sensibility. Because of the positive Wassermann reaction of the blood and because of the previous carcinoma of the breast, a diagnosis of myelitis that was the result of one or the other condition was made, and the patient was allowed to return to her home, after antisyphilitic treatment had been advised. She received treatment at home, and while she was being treated the numbness improved and she was able to drive a car and walk. This treatment was continued for eight weeks. Two weeks after the treatment was discontinued, the numbness of the legs increased and it became difficult for her to walk. Her condition gradually became worse until she was confined to her bed and was unable to move even her toes. She returned to the clinic for reexamination, at this time there was almost complete paralysis of the lower extremities, and a definite sensory level could be demonstrated corresponding to the sixth thoracic segment. Examination of the spinal fluid proved that the Wassermann reaction was negative, there was a positive subarachnoid block. Roentgenologic examination of the spinal column did not reveal any evidence of metastasis. Laminectomy

tomy was performed, a large meningioma was found opposite the fourth interspace. It was attached to the right side of the spinal cord, which was compressed to about a fifth of its normal size. The tumor, which was removed with its dural base, measured 3 by 2.5 by 1 cm. An uneventful convalescence followed, and there was a gradual restoration of both sensory and motor functions of the lower extremities, at the expiration of seven months the patient was walking about.

Like metastatic lesions of the spinal cord, primary malignant tumors of the spinal column and contiguous tissues are infrequent, and even if there is evidence of destruction of the bone in the roentgenograms it sometimes is advisable to operate and remove as much of the tumor as is possible and then employ radiation therapy in an attempt to relieve the compression of the spinal cord and to control the growth of the tumor. Following this type of procedure, the results are sometimes more than gratifying, as illustrated by the following case.

A youth, aged 20 years, came to the clinic complaining of difficulty in walking, which had been present for the previous year and a half. At the onset of his trouble he first had noticed pain just under the left scapula. The situation and level of the pain had remained constant. The pain had extended anteriorly as far as the anterior border of the axilla. It had been worse at night than it had been during the day, and it had become more severe when he coughed or sneezed. The pain had continued without change for one year, when he had noted stiffness about the hips, and a periodic dragging of the left leg, which had been associated with numbness. One month previous to his examination at the clinic his legs had become very stiff and weak, and he had been unable to get up and about. Roentgenologic examination of the spinal column revealed slight scoliosis of the upper thoracic vertebrae, an irregular mass which involved the left side of the lamina of the third thoracic vertebra, and destruction and proliferative changes, which caused a diagnosis of questionable osteochondroma to be made. The neurologic examination revealed weakness of the muscles of the back and lower extremities below the eighth and ninth thoracic segments, an increase in reflexes of the lower extremities, and the presence of ankle clonus. Babinski's reflex was present on both sides and there was evidence of marked incoordination and spasticity. There was almost complete loss of sensation below the level of the second thoracic segment, and there was loss of vibration and joint sensibility in the lower extremities. Lumbar puncture did not reveal any change in the pressure of the cerebrospinal fluid, following compression of the jugular veins. Because of the subarachnoid block and the localizing level, laminectomy was performed. This revealed a bony mass between the spinous processes of the third and fourth thoracic vertebrae. Microscopic examination revealed that the tumor was an osteogenic sarcoma. The laminectomy was completed by removing the spines and laminae of the third and fourth thoracic vertebrae. A discrete mass could be seen lying on the left side and compressing the cord opposite the intervening interspace. The entire mass was removed, although the adjacent bone was involved in the process. Following the healing of the wound, the patient was given one course of high voltage roentgen therapy in four treatments. He returned to the clinic six weeks later for a second course of roentgen therapy. At that time there was subjective and objective evidence of definite improvement. He was able to walk, but some spasticity still was present and he still complained of pain which was induced by coughing or sneezing. He again returned to the clinic six weeks later, at that time it was found that the improvement had continued and that the loss of sensation extended only to the level of the hips. Vibration and sensibility had begun to return, and the spasticity had decreased. He was given a third course of high voltage roentgen therapy. When he returned to the clinic seven months later, examination revealed that his condition had returned to normal. At this time roentgenologic examination of the spinal column revealed some proliferation about the left lateral margin of the laminectomy wound, but there was no evidence of a tumor.

SYMPTOMS OF ARTHRITIS

Among the more common general conditions with which tumors of the spinal cord may be confused is arthritis. In many cases in which a tumor of the spinal cord is suspected, the only demonstrable lesion in the roentgenograms of the spinal column consists of hypertrophic changes in the vertebrae. Sciatica and pain in the lower part of the back sometimes constitute the only symptoms for a long time, and the diagnosis can be made only after very careful study. Hench⁴ has called attention to the fact that, in any case of arthritis in which morphine or codeine is required to relieve the pain, a tumor of the spinal cord should be suspected.

A woman, aged 45, came to the clinic complaining of pains, which were situated over both sacro-iliac regions and which extended down to the ankles. She had had acute rheumatic fever at the age of 8 years, and four years before her examination at the clinic she had had an attack of arthritis, which had involved the knees, wrists and fingers. Two years previous to her examination she had had an attack of severe pain over the sacro-iliac joints, since that time she had had periodic attacks of pain, which had extended to the buttocks, groins and pelvis. There also had been some pain in both ankles. These attacks had lasted two weeks and then had disappeared. The attacks, however, had become more frequent and had appeared closer together, the last attack had kept her awake for three nights.

Roentgenologic examination of the spinal column revealed some hypertrophic changes about the sacro-iliac joints. The neurologic examination did not reveal any abnormality. She was hospitalized to be treated for arthritis but, because the pain became so great when she was in bed, a spinal puncture was done to rule out the possibility of a tumor of the spinal cord. The cerebrospinal fluid was yellow and there was a complete subarachnoid block. Following the spinal puncture there still were no localizing signs, and for that reason, 5 cc of iodized poppy-seed oil was injected into the subarachnoid space through the posterior cistern. Roentgenoscopic examination revealed that the iodized oil had descended to the level of the twelfth thoracic and first lumbar vertebrae. The column of oil was divided, and in the subsequent roentgenogram a definite tumor could be outlined. For that reason a laminectomy was performed. This involved the twelfth thoracic and the first, second and third lumbar vertebrae. Large multiple neurofibromas were found attached to the second lumbar root. Following the operation the patient made an uneventful convalescence and the pain was completely relieved.

PAIN

Of extreme interest to general surgeons should be the painful syndrome of tumors of the spinal cord, because it is in this phase of development of these tumors that the patients usually insist on having something done to relieve the pain. The gallbladder or appendix always is suspected of causing pain that extends to the upper or lower right quadrant of the abdomen, and pain that extends to the pelvis may be associated with an ovarian cyst or a fibroid, but after the suspected lesion is removed, pain is still present. What really emphasized this feature of tumors of the spinal cord was the following case.

A man came to the clinic because of pain, which extended to the region of the gallbladder. A diagnosis of cholecystitis was made in the face of negative results of the general and neurologic examinations. This was based on the distress after eating and on the positive roentgenologic evidence of disease of the gallbladder. The pain persisted following cholecystectomy, and no explanation could be found for the persistence of the pain. When he returned to the clinic six months later, there was an unmistakable Brown-Sequard syndrome, which

⁴ Rynearson, E. H., and Hench, P. S. Rheumatism That Requires Morphine. *M. Clin. North America* 15: 153-161 (July) 1931.

indicated that the trouble was within the spinal canal. A large intradural extramedullary neurofibroma was removed, and there was complete cessation of symptoms.

It was interesting to note that 10 per cent of the patients who have been subjected to operation for tumors of the spinal cord had been operated on previously for the relief of the pain or disability. To emphasize this point further, two cases are presented briefly, as they both have been reported previously.

The first case does not differ in many respects from countless others in which pain extends to a region in which examination reveals a local lesion. In the absence of any neurologic signs, there was little reason to suspect a tumor of the spinal cord in this case, except that the pain was relieved by exercise.

A woman, aged 37, came to the clinic complaining of an intermittent drawing pain, which was situated in the left lower part of the thorax and in the abdomen and had been present for two years. The pain had been increasing in severity, it had not responded to any type of treatment but it had been relieved by exercise. Six months after onset of the pain, examination had revealed the presence of an ovarian tumor and laparotomy had been performed for relief of the pain. Because the pain had been projected at times to the right side of the abdomen, not only a left cystic ovary and the corresponding fallopian tube had been removed but the appendix also had been removed. In the course of convalescence the pain had returned with the same severity. No obvious cause could be found for the pain, but about six months after operation the patient had noticed a drawing pain in her left leg and some weakness of the muscles of both legs. Examination at the clinic two years after the onset of pain and a year and a half after operation revealed sensory and motor changes corresponding to disturbance of the right thoracic segment. Removal of an endothelioma of the spinal cord relieved the weakness, anesthesia and pain.

Tumors that affect the lumbar portion of the spinal cord are the most difficult to diagnose and localize. In this region a tumor may produce pain, weakness, atrophy or all three, for a long time, with no other objective evidence. When a tumor of the spinal cord is not suspected, restorative measures are sometimes carried out.

A man, aged 43, came to the clinic complaining of an aching distress in the sacro-iliac region which had extended down the left thigh and had been present for three years. Six months after the onset of pain, atrophy had developed in the left thigh and leg; this had resulted in marked weakness and disability of the parts affected. The pain had persisted, had been variable in nature, and had been intermittent. Two and a half years after the onset, the pain had proved of little consequence in comparison to his disability, for which he sought relief. In spite of the pain a diagnosis of residual poliomyelitis was made and a tendon transplantation was done. This operation seemed to cause gradual increase in severity of the pain, until the patient was unable to sleep in bed. It was necessary for him to sleep in a chair. Examination which was conducted six months after operation, revealed marked weakness below the gluteal muscles on the left side and some weakness on the right side. The patellar and the achilles reflexes were absent on both sides. There was loss of pain temperature and tactile sense over the left calf. The cerebrospinal fluid was yellow and there was no change in pressure following compression of the jugular veins. At operation multiple neurofibromas, which extended from the first to the fifth lumbar vertebra, were removed. This operation caused the symptoms to disappear.

COMMENT AND SUMMARY

Tumors of the spinal cord may simulate other neurologic lesions or the neurologic manifestations of constitutional diseases or infection. The painful syndrome, which is present in 80 per cent of the cases, may persist

for months or years and may simulate diseases of the pericardium and pleura, diseases of the biliary, urinary and gastro-intestinal tracts, and diseases of the peripheral nerves, muscles and bones. The majority of tumors of the spinal cord are benign and operable. If tumors of the spinal cord are removed before they produce irreparable damage to the spinal cord, a restoration of function almost always follows. Operation for the removal of tumor of the spinal cord is attended with a mortality of less than 4 per cent.

ABSTRACT OF DISCUSSION

DR. ERNEST SACHS, St. Louis. Dr. Craig has emphasized the early diagnosis and has pointed out and given striking examples of cases that were readily confused with some other type of condition. In going over our series of spinal cord tumor cases with this particular idea in view, I noted that whereas in the typical spinal cord tumor case pain is one of the earliest symptoms, there were a number of cases in which pain was not the initial symptom. Many of these patients gave a history that after seeing their physicians and obtaining no relief they had gone to quacks, osteopaths or chiropractors. The first symptom that these patients complained of was a peculiar paresis or anesthesia. However, owing to the fact that the general physician doesn't devote much time to a careful neurologic examination, the slight changes in the nervous system had not been noted. One patient, the brother of a physician, presented himself with the symptom of painful urination and difficulty in emptying the bladder. The physician concluded that the difficulty was due to some prostate trouble and removed his prostate without any relief. I saw the patient shortly afterward and at that time he had almost complete retention. The only neurologic symptom he had other than the bladder disturbance was saddle anesthesia. In an ordinary physical examination this can be readily missed. The patient had a large extradural fibroma of the lower portion of the spinal cord. On removal of the tumor the patient's symptoms completely cleared up. Another patient was a woman who complained for over a year that she could not take a cold bath and that whenever she got any cold water on her abdomen it produced excruciating pain; this was considered a neurosis. I saw her repeatedly and made sensory examinations suspecting a spinal cord tumor, but I wasn't able to arrive at any definite decision until instead of making sensory examinations with cotton and a sharp needle I used a piece of ice, when it was perfectly easy to establish a definite line of changed sensation on one side of her abdomen. She had a neurofibroma growing from one root. With its removal these paresthesias disappeared. There is no relationship between prolonged neurologic symptoms, compression of the cord, and the possibility of the spinal cord recovering after long compression. All have seen cases in which a spinal cord has been compressed for a long time and was almost ribbon-like in character, yet such a patient might recover completely, while other patients who have comparatively slight compression of the cord may not recover their motor or sensory functions to any extent.

[DR. WINCHELL MCK. CRAIG, Rochester, Minn., showed moving pictures of a patient before and after operation, presenting the classic symptoms of tumors of the spinal cord. The picture showed preoperative examination, drawings of the operation, and postoperative examination showing partial recovery after an interval of twenty-one days. Complete recovery was shown after an interval of three months.]

Body Fat—A superfluity of food leads either to indigestion or to undue fatness—sometimes to both. Too meager a food intake depletes the body of such stores of fat as it should normally carry. Body fat has important functions: it constitutes a reserve supply of fuel, it serves as a support for some of the internal organs, notably the kidneys, and it may at times be of great service in protecting parts of the body from bruises or from cold.—Sherman, H. C. *Food and Health*, New York, Macmillan Company, 1934.

BASAL MENINGITIS

SOME CONSIDERATIONS AND A PROPOSED
MANAGEMENT

FERRIS SMITH, MD

GRAND RAPIDS, MICH

I have been impressed, during a period of many years, with the variation of the postmortem picture at the base and on the cortex after meningeal death. All physicians have noted many times the well organized exudate at the base of the brain and the thin, flocculent purulent exudate that covers the pia in the sulci and on the surface of the brain. It was certainly twenty-five years ago that I was first struck with this observation, but it has only been within recent years that I have been impressed with the significance of it.

This well organized exudate represents the point of entrance of the infection and nature's effort to confine it. It is the sign post pointing to the field which is to be considered here. The floor of this involved area is the roof of the posterior ethmoidal cells, the sphenoid sinuses and the basilar process of the sphenoid bone.

The essential anatomy of this region must be carefully reviewed, some teachings in relation to it discarded, and a mental picture of the circulation of the area acquired in order that the sequence of events which lead to a meningitis may be fully appreciated.

It has been taught that the principal blood supply of the sphenoid sinus comes from branches of the vessels supplying the pharyngeal mucosa as this structure follows pneumatization to line the cavity. Physicians have further been led to believe until recent years that there was no connection between this blood supply of the cavity lining and the intracranial structures. Nothing can be further from the truth (fig 1).

Breschet in 1837 fully demonstrated the circulation of the base and of the vertebra. If the occipital and sphenoidal bones may be regarded as the first two segments of the vertebra, there will be no difficulty in picturing its blood supply. The arrangement is apparently identical with that of the vertebral segments. There is free communication between the vessels of the sphenoidal lining and the haversian systems of the basilar process and between these systems and the dura, which dips through the cortex of the bone to connect with parts of this arrangement in the marrow. Logan Turner¹ clearly demonstrates this in his studies of the pathways of infection. There are numerous fine veins which terminate in the dura or join the basilar veins and do not traverse the arachnoid to the pia mater. There are other veins which pass either directly or indirectly to the latter structure. Secondly, there is direct vascular communication between the cortical bone on the roof of the sphenoid and its dural covering. Thirdly, there is free communication between the veins of the sphenoid lining and the basal venous pools both directly and through the pterygoid plexus and its branches connecting with the cavernous sinus. These venous lakes at the base of the brain, that is, the cavernous sinus, the circular sinus, the basilar plexus, the inferior petrosal veins and so on are all parts of one system which have been variously named.

The perilymphatic sheaths of the arteries at the base are arachnoid prolongations which follow them to their terminations.

The consideration of the cisterns at the base is essential. These again are variously named but are in fact interconnecting and intimately related. The basal cistern is the space between the arachnoid and the pia mater resulting from failure of the arachnoid mater to follow the surface of the brain across the base from one temporal lobe to the other. Included in this is the pontine cistern, which is a similar space just anterior to the pons, also the chiasmal cistern resulting from a similar failure of the arachnoid to follow the surfaces of the branches of the optic chiasm. This basal cistern connects posteriorly with the cerebellomedullary cistern or the cisterna magna. It is in the area of this so-called basal cistern that one notes the old, well organized exudate in the fatal meningitis case of basal origin. This is obviously the point of entrance of the infection.

Pickworth² has demonstrated organisms in the sphenoid lining and similar organisms in the haversian veins, in the bone cortex, in the dura, in the capsule and substance of the pituitary gland, in the perilymphatic sheaths of the arteries, in the artery walls and in the perineural sheaths of the base.

Fig 1—Injection of the sphenopalatine artery illustrating the absence of demonstrable branches supplying the sphenoidal sinus lining. (Preparation made by Dr. William C. MeLOY while a member of the author's staff.)

With this definite picture of the modes of entrance of infection in mind, one has only to consider the physiologic and pathologic processes that follow an extension of infection from the sphenoidal cavity in order to complete the picture. The organisms may extend by continuity, on the one hand, or be carried through the veins by a process of thrombophlebitis, on the other. There may be presented an osteoporosis, an osteitis or an osteomyelitis in the early stages. Either of these invasions may continue until the veins of the dura and the basilar plexus are included in the process. It is at this point that the physiologic action of the pia arachnoid produces a barrier more or less temporary, depending on the virulence of the infection to the further extension of the disease process. Eagleton³ points out that "this frame work is not only a barrier, but also contains a protective mechanism, so that any infection which may pass the barrier of the

dural covering or which may be brought to the brain by the circulatory blood, will be instantly counteracted, digested and removed." He states further that "if we are to understand meningitis, we must understand this framework, this barrier, this protective mechanism, this phagocytic membrane not only in its gross anatomy, but also in its microscopical physiology and especially its reactions in the presence of an irritant via trauma, cold or micro-organisms."

Fig. 2—X-ray study of the base showing an early osteomyelitis involving the basilar process and the occipital articulation. There is beginning bone absorption and rarefaction. There is marked opacity in the sphenoid sinus.

well organized exudate at the base is found. It is only when the infection involves the veins or follows the arterial sheaths traversing the pia that the barrier is broken down and that the infection produces a fatal leptomeningitis.

The interest of the physician centers in the events from the moment of initial infection to a time prior to the extension of the infection beyond this circumscribed area. There is a period, depending on the virulence of the invading organism or from one to forty days in which to recognize the situation and carry out its management.

Fig. 3—Illustrating conditions present in figure 2 and the position of the burr in draining the pontine cistern.

The clinical picture is definite and typical. It is frequently ushered in by a feeling of malaise, a dull, heavy sensation behind the eyes, or an orbital neuralgia. There may also be pain in the supra-orbital, malar and mandibular regions. As the disease progresses, the patient lies on his back with his eyes closed in a state of semicomatose from which he is easily aroused. He may or may not complain of pain in the neck but does

not have stiffness of the neck until the cisterna magna becomes involved. Repeated examination reveals an intermittent, recurrent, vertical nystagmus and occasionally similar behavior in the horizontal plane. There may be paresis or paralysis of the sixth nerve. There is a slight elevation of temperature and a moderate leukocytosis. The spinal fluid is under slightly increased pressure, is usually cloudy and presents an increased cell count. There may or may not be bacteria in the fluid at this stage.

It becomes apparent that during this distinct phase of the disease any management which will afford free drainage and the restoration of normal circulation offers the possibility of saving many lives which are now almost invariably lost. The requirements will consist of drainage of the basilar process of the sphenoid or of such drainage, plus drainage of the basal cistern, according to the extent of the disease.

I present for consideration two methods of approaching this problem and the outcome of three such surgical attempts.

CASE 1—E. M., a woman, aged 33, an anesthetist, who entered the hospital May 24, 1933, had pansinusitis over a period of fifteen years. There were twelve operative pro-

Fig. 4—Position and direction of the burr for drainage of the pontine cistern. See figure 3.

cedures for relief of empyema, frontal abscess and exacerbations of osteomyelitis during this period.

The present condition began with a coryza ten days previously. The first complaint was headache of a mild character. This was soon complicated by several days of intermittent "aching" and pain behind the eyes, lassitude and malaise. The retrobulbar pain increased in intensity until it could not be controlled by opiate, and tribrom-ethanol was required for the patient's rest.

There was a temperature from 97 to 99.5 F., with a pulse rate of 100. The patient remained flat on her back. She was drowsy but easily aroused and she complained of pain in the occipital and upper cervical region. She preferred a darkened room because of a mild photophobia. She presented an intermittent spontaneous vertical nystagmus. The spinal fluid was under slight pressure, slightly cloudy and contained 1800 cells. The leukocytes numbered 17,250 with 91 per cent polymorphonuclears, 7 per cent large lymphocytes and 1 transitional cell.

The involvement of the sphenoid sinus, the basilar process of the sphenoid and the articular process of the occipital bone is illustrated in x-ray studies shown in figures 2 and 3.

The rapid development of the symptoms and the fluid changes demanded immediate action if any were to be taken. A choice had to be made between two long contemplated approaches.

An intranasal trans-sphenoidal route was selected because of the chronicity of the history, the fact that the opposite cavity had been the site of complete surgical operation for chronic disease and the apparently old pathologic condition in this sphenoidal cavity which demanded removal as well as an adequate drainage of the basilar process and basilar cistern.

The sphenoidal cavity and the bony floor were treated as previously described.⁴ A burr of three-sixteenths inch diameter was introduced in the midline at an angle directed toward the middle third of the pons (fig 4). The burr was driven into the bone for three eighths inch and then exchanged for a slightly smaller one. This provided a stop for a tube to be introduced after the dura had been opened.

The smaller drill was driven through the medullary and superior cortical bone to the dura. The drill was removed and

The drilling and subsequent procedure are carried out as described in case 1. There is much less danger of injury to the internal carotid arteries in this approach than in the trans-sphenoidal one. The operation is concluded by closure of the velum with horsehair sutures.

CASE 2—P. E., a boy, aged 6, admitted Jan. 21, 1934, had an infection of the upper respiratory tract eighteen days before admission. Acute suppurative otitis media developed three days later. Intermittent drainage occurred from the ear and, later, spontaneous drainage through an old mastoidectomy scar. The patient was very irritable and complained of frontal and occipital headache with stiffness of the neck.

There were increased muscle tonus in both upper and lower extremities, hyperactive biceps, triceps, knee and achilles reflexes, positive Kernig's sign, stiffness of the neck with pain on motion, normal extra-ocular muscle and pupillary action, acute suppurative otitis media and suppurative mastoiditis (left). The spinal fluid was under normal pressure and was cloudy, it contained 1440 cells, the phenol test was + + +, Nonne-Apel't tests were + + + and + +, with no organisms on smear and culture. The temperature was 103, pulse 118. Leukocytes numbered 15,150, with 88 per cent polymorphonuclears. Blood culture was negative. The urine had a specific gravity of 1.024, albumin +, leukocytes 25. Culture from the ear yielded *Staphylococcus aureus*.

I saw this patient in consultation with Dr. Lee Grant twenty-four hours later. The clinical picture was only slightly changed. There were marked photophobia, no rigidity of the neck, a spinal fluid cell count of 630 and no bacteria. X-ray examination of the mastoid that had been operated on revealed the presence of cells over the entire mastoid and in the root of the zygoma. The operative note of Dr. Grant on this date stated that considerable necrosis had occurred in the area of the middle ear and the mastoid antrum. Infection was present throughout the mastoid, with areas of sclerosis. Marked regeneration of cells followed the previous operation.

There was a slight remission in fever, cessation of drainage and some general improvement for a few days following this operation.

I again saw the patient in consultation seven days later. He complained of pain behind the eyes and photophobia. He presented both a spontaneous horizontal and vertical nystagmus, no

Fig 5—Temperature, pulse and respiration in case 1

the dura opened. A soft tube having the same diameter as the initial drill (three sixteenths inch), was passed through the nose and into the drill hole. This was clamped external to the nostril.

The sudden loss of fluid when the dura was opened plus the local trauma, caused an immediate marked disturbance of respiration and pulse. This corrected itself shortly after the clamping of the tube and stimulation by carbon dioxide.

There was a sharp increase in the temperature, pulse and respiration a few hours after the operation and a gradual decline to normal during the subsequent three days. These variations probably resulted from the trauma and the presence of a small quantity of free blood (fig 5). The blood pressure showed little variation (118/68). The patient was very restless and complained of intense general headache for forty-eight hours. The pain about the left eye disappeared during the first twenty hours. She was nauseated and continued to complain of pain in the vertex and occiput for several days. She was discharged on the tenth day.

In the following cases drainage was accomplished through a transoral approach (fig 6). This is less technical (less time consuming) and should meet the requirements of most cases. The velum is incised from the posterior margin of the palate bones to the base of the uvula. The proximal end of this incision is continued laterally on both sides along the edge of the palate bones to the hamular processes. Retraction of the incised velum exposes the vault of the nasopharynx—the basilar process of the sphenoid bone and its occipital articulation. A T shaped incision is made in the midline and the soft coverings are separated to expose the bone just posterior to the rostrum of the vomer (fig 7). The sphenoid cavity is opened from below.

Fig 6—Position and direction of the burr for the transoral drainage of the pontine cistern

weakness of the extra-ocular muscles, slight stiffness of the neck and a positive Kernig's sign. The leukocytes numbered 28,650, with 88 per cent polymorphonuclears. The spinal fluid was under slightly increased pressure, was cloudy and contained 1920 cells. The sediment presented a very occasional pair of gram-positive cocci. There was no growth on the culture at the end of twenty-four hours and a few colonies of hemolytic streptococci at the end of forty-eight hours. I advised further

⁴ Smith, Ferris. Management of Chronic Sinus Disease. Arch. Otolaryng. 10: 157-171 (Feb.) 1934.

exploration of the mastoid and drainage of the basal cistern. Soft bone was removed from the tip, the sinus plate, the root of the zygoma and the depth of Trautman's triangle. The base of the petrous bone was normal. A liberal area of dura about the petrous bone was exposed and found negative.

The cavity of the sphenoid, its basilar process and the pontine cistern were drained as described.

The temperature and pulse variation during the first four postoperative days is graphically depicted in figure 8. Compare with case 1, figure 5. The fluid cleared of staphylococci under

Fig. 7—Opening of the velum and of the nasopharyngeal soft parts to expose the basilar process of the sphenoid.

direct treatment with bacteriophage but streptococci remained in the sediment. The patient's subjective symptoms largely disappeared during these four days and there was marked improvement in the objective signs. The temperature and pulse rose rapidly on the fifth postoperative day and the child died suddenly in a convulsive attack.

The autopsy report is partly as follows: About the brain stem at the base there was a purulent exudate. The entire area of this was not more than 5 cm in diameter. This area centered in the region of the lower pons and here there had been extensive exudate organization. There was marked obstruction to the circulation of spinal fluid in the region of the fourth ventricle and its foramen which in turn produced an extensive obstructive internal hydrocephalus, all of the higher ventricles being tremendously distended by a slightly cloudy fluid. The anatomic diagnosis was acute meningitis, localized acute obstructive internal hydrocephalus.

Microscopic examination of sections of the cord, pons and medulla showed marked inflammation. The extent of this tissue reaction was such as to point to the fact that this inflammation had been present for some time. There were areas which showed necrosis of abscess formation. There was some reaction in the superficial layers of the brain tissue characterized by a perivascular infiltrate extending along the lymph spaces of the blood vessels into the pons and medulla. The condition found indicated an attempt at localization of the infection. The degree of organization changes pointed to infection being present for some time.

The clinical picture in case 2 contrasts strongly with case 1. The stiffness of the neck and the presence of a positive Kernig's sign, evidence involvement of the cisterna magna. The marked irritability, headache and hyperactive reflexes suggest vascular extension of the infection. The infection is no longer walled off at the site of invasion. The patient should have been operated on earlier.

The third patient was a poor surgical risk. The case serves to emphasize the necessity of early diagnosis and immediate drainage.

CASE 3—G. M., a woman, aged 28, a nurse, entered the hospital Jan. 18, 1934, complaining of constant frontal and vertex headache and pain in the left side of the neck, the occipital region and the left ear canal, chronic sore throat, a nasopharyngeal purulent drainage, polyarthritis and diabetes. She had had sinus disease for fourteen years. Numerous sinus operations failed to give relief. Tonsillectomy and appendectomy had been performed. She had had diabetes for several years.

Physical examination was negative, except for the upper respiratory tract. The nose and the nasopharynx contained thick mucus. The right ethmoid labyrinth had been completely exenterated. There were some ethmoid cell remnants and small polyps on the left side. Both antral cavities were open into the nose (Caldwell-Luc). Both frontal ducts were widely open. The anterior walls and part of the floor of both sphenoidal cavities had been removed. There were deep pterygoid pneumatizations on both sides and several small cavities in the basilar process, which could be explored with a probe. A thick, pyogenic membrane covered the remnant of the sphenoidal cavity. There was a spontaneous nystagmus in every plane. The horizontal nystagmus was most marked and that in the vertical plane was mixed in type.

X-ray study of the base presented only a very dense picture and little useful information.

The temperature was 98, pulse 80, respiration 20. The spinal fluid was cloudy and contained 190 cells. The phenol test was ++. Nonne-Apel't tests were +++ and 2 +++ with no bacteria. Leukocytes numbered 7,500. The urine was acid, with a specific gravity of 1.027, there was a slight trace of sugar. Tests for acetone and diacetic acid were negative.

The operative management was the same as described in case 2. The drill opened two cavities containing pus in the marrow of the basilar process. The effect on the temperature, pulse and respiration is shown in figure 9.

Fig. 8—Temperature, pulse and respiration in case 2 during the first four days after operation.

The characteristic pain diminished during the first few postoperative days and the patient was definitely improved. Sugar, acetone and diacetic acid were present in the urine on the second postoperative day and continued in varying amounts for eleven days. The bowel condition was difficult to manage. These two facts suggested involvement of the pituitary gland and a definite diagnostic point for consideration.

The temperature varied from 1 to 1.5 degrees daily for seventeen days. There was slight variation in the leukocyte count until the eighth day, at which time they increased to 12,000.

with a polymorphonuclear count of 92 per cent. The count increased to 29,400 on the twelfth postoperative day. The spinal fluid remained practically the same as originally noted except that on two occasions isolated colonies of staphylococci were reported as probable contaminations.

The patient was about her room from the fifth to the tenth postoperative day. She constantly complained of increasing occipital headache, to which was later added bitemporal pain.

The clinical picture changed suddenly on the nineteenth postoperative day. There were several indications of cerebral extension. The patient became stuporous on the following day and died on the twenty-third postoperative day.

On postmortem examination the pia-arachnoid and dura were very adherent and thickened in the region about the pons and medulla. Adhesions were so dense in this area that the brain was dissected free by the knife only. The ventricles were not distended. The deeper brain structures showed no important pathologic changes. The endosteum was very much thickened over the base of the skull and there was an accumulation of pus over the bone above the orbital plate particularly on the right side. The inflammation and tissue reaction emanated from the sphenoid bone. The surgical drainage area was demonstrated in the middle of the sphenoid which lay adjacent to a point corresponding to the lower third of the pons. The sphenoid bone was explored. There were several cavities within this bone containing pus and showing bone necrosis. The density and the age of the inflammatory reaction in the tissues adjacent to the sphenoid bone implied that this inflammation had been present for a long period and that there was superimposed on the older process an acute pyogenic inflammation.

Microscopic examination of sections of bone from the sphenoid region showed an extensive old osteitis with areas of bone proliferation and areas of bone destruction. Sections of brain from the base showed an old meningeal productive inflammation of low grade, showing marked proliferation with fibroblasts and thickening of the arachnoid and pia accompanied by proliferation of blood vessels. Superimposed on this process there was an acute pyogenic meningitis with areas of necrosis and accumulation of abundant fat. The nervous tissue lying beneath the process described showed a mild glial proliferation and accumulation of inflammatory wandering cells about the blood vessels.

The diagnosis was chronic osteitis of the sphenoid bone, chronic leptomeningitis with superimposed acute pyogenic meningitis.

These three cases present distinct phases of the same process. The clinical picture in the first case resulted from early inflammation with congestion, without the demonstrable presence of organisms, involving the veins and the dura of the middle fossa and the anterior portion of the posterior cistern.

It is my impression that the "aching" and retrobulbar pain depend on venous congestion. The relief is too rapid for a subsiding inflammation. The same rapid disappearance of these symptoms is frequently noted after a complete mastoidectomy. The pain in the neck results from superficial inflammation of the brain stem. Confinement of the process to this limited area by adhesion of the pia arachnoid had occurred in the first case.

The disease process in the second case had already passed this protective barrier when the patient was hospitalized. The cisterna magna was already invaded and the infection was already following the vessels into the brain substance, as evidenced by the symptoms noted. The rapidity of this invasion depended on the virulence of the organisms and other obvious factors, but it is highly probable that there was a definite period during which characteristic signs and symptoms indicated confinement of the invasion to an area that may be drained. The early appearance of a suppurative otitis might divert attention from the true picture.

The chronicity of the disease in the third case, as indicated by the history and the microscopic examination, is positive proof of the ability of the pia-arachnoid to confine infection for varying periods of time to the

area noted. There was obviously a time in the progress of this case when the bone and the pontine cistern could have been drained with probable success.

CONSIDERATIONS

1 An early diagnosis is obviously essential. One might draw a parallel with the diagnosis of appendicitis. The recognition of the early signs and symptoms and prompt intervention before the peritoneal barrier is passed has practically reversed the mortality rate.

2 Intratracheal anesthesia is advisable. It permits not only protection of the respiratory tract during operation but also immediate stimulation, if required.

3 It is my belief that this is the ideal method of draining infections extending from the petrous tip, as well as those originating in the sphenoid sinus. It is not only much simpler than the other approaches described but also provides dependent drainage.

Fig 9—Temperature pulse and respiration in case 3

Eagleton⁵ states that "infection of the petrous apex—from caries—enters directly into the pontine cisterna, in which area it is readily limited and to which it may be confined for a considerable time."

4 There is a considerable sudden loss of spinal fluid, despite the fact that the tube is in position for rapid introduction on removal of the instrument from the bone opening.

5 The dangers of this sudden loss of fluid are

- (a) A sudden disturbance in the equilibrium between the intracranial and the intermedullary capillary pressures, which may result in an ischemia of vital centers sufficient to cause death.
- (b) Embarrassment of respiration of varying degree. Preparation for stimulation and artificial respiration should be at hand.

6 It is my belief that the fluid should be slowly withdrawn until the drainage is complete. This will relieve local congestion and aid in putting the area at rest. It will also permit greater collapse of the space and more complete "walling off."

⁵ Eagleton W. P. The Cerebrospinal Fluid. J. Laryng. & Otol. 44: 660 (Oct.) 1929.

7 Treatment

A Operative

- 1 The involved sinus mucosa and bone must be drained. This may be adequate for a cure in early cases. Such a result is frequently noted in cases of mastoiditis.
- 2 The basal cistern must be drained when the indications are present.

B Postoperative

- 1 Direct intra-arachnoid medication is dangerous. It produces collapse and suspends respiration.
- 2 I have used bacteriophage at body temperature with a striking result.
- 3 Eagleton⁵ states that irritating antiseptics paralyze respiration, solutions which are not isotonic cause a rise of temperature to 105 or over, that temperature below that of the body suspends respiration, and that free blood in the cistern produces all the clinical manifestations of meningitis. There is a slight amount of free blood immediately following incision of the dura but the fluid rapidly becomes free of it.

It is my hope that these considerations will awaken sufficient interest in accumulating an experience in this field to produce a standard management. This should result in saving many lives.

Blodgett Medical Building

THE TREATMENT OF EARLY SYPHILIS WITH ELECTROPYREXIA

CLARENCE A NEYMANN, MD

THEODORE K LAWLESS MD

AND

S L OSBORNE BPE

CHICAGO

Medical history is replete with stories of the resurrection of ancient formulas and therapies. From time to time the most modern researches have extracted the essence from gleanings of empirical therapeutic methods, superstitions and medieval nostrums. Such reanimated knowledge has often given a new impetus to the entire field of therapeutics. It is as if the dust of ages were shaken from the golden threads of a fine garment, and these threads then respun into a glittering vestment to serve present needs.

The empirical treatment of syphilis by means of heat harks back to the beginning of the sixteenth century, when this disease had been spread over much of Europe. During this period, this scourge was fought with various forms of heat. Sometimes thick blankets and hot baths were used alone, more often these were employed in conjunction with drugs, especially mercury. As late as 1872 very hot stove-heated rooms were used in Montpellier, France, in which patients suffering from syphilis were confined.¹ Very little, if any other medication was employed and after a number of weeks the patient was discharged apparently cured that is to say, relieved of his acute symptoms. In 1889 Kalashnikoff²

wrote that following the experiments of Borowka under the direction of Tarnowsky at St Petersburg he treated many local manifestations of syphilis with heat. Whenever the lesions were found in the extremities, these were immersed twice daily in a bath at a temperature between 47.2 and 47.7 C (117 and 117.9 F) for thirty minutes. If the lesions were situated in the more inaccessible parts, such as the buttocks, the face or the genitalia, hot fomentations or hot water bottles with temperatures varying from 46.1 to 48.8 C (115 to 119.8 F) were applied twice daily for one hour. The syphilitic lesions treated in this manner disappeared more rapidly than when they were treated with the mercurials then in vogue. If mercury was combined with heat, even a more prompt dissolution of the lesion resulted. Kalashnikoff falsely attributed this action to an increase in circulation but correctly concluded that this local therapy was not a cure of the basic disease. However, he was well aware of the fact that heat in itself destroyed the syphilitic virus.

Lately, many new facts have been established which throw additional light on the effects of heat and fever in the treatment of syphilis. It is now well known that spirochetes found in primary and secondary lesions both of man and of animals are destroyed by heat. Boak, Carpenter and Warren³ established the death point of spirochetes in vitro as 41 C (105.8 F) maintained for one hour. They also stated that even lower temperatures are lethal to this organism if maintained for longer time intervals. Carpenter and Boak⁴ also stated that rabbit syphilis could be cured by febrile temperatures ranging between 41 and 42 C (105.8 and 107.6 F) if several bouts of fever lasting approximately six hours were given. This work was preceded and followed by the investigations of Bessemans and his collaborators. The conclusions of these scientists are of such great importance that we will give a survey of their theories later on and couple them with our own experiences in treating primary and secondary syphilis with hyperpyrexia. Levaditi, de Rothschild,⁵ Audard, Haber, Vaisman and Schoen also admit that there is a direct curative effect of electrically produced fever on both the syphilomas of rabbits and systemic rabbit syphilis.

Bessemans and his collaborators⁶ recognized the importance of local heat for overcoming the infectious potency of chancres and other external and internal syphilitic lesions long before the work of the aforementioned investigators had been begun. The first investigations of Bessemans were published in 1929. Later, Bessemans and Thiry⁷ proved conclusively that spirochetes became immobile and disappeared from the lesions of human syphilis and that the lesions themselves healed after heat had been applied by means of the diathermic current. They also showed that the control lesions on the same patient which were not treated

either increased in size or remained stationary. The internal temperature of all these lesions, as recorded by means of a thermocouple inserted into them, varied roughly between 41 and 43 C (105.8 and 109.4 F). These temperatures were maintained between thirteen and eighty minutes by a constant application of the diathermic current. It was therefore established that local syphilitic lesions of man can be healed by heat and that the spirochetes disappear from lesions treated in this manner.

In the course of the earliest researches with hyperpyrexia, and shortly after we⁸ had introduced and originated this therapy, one of us⁹ treated two male patients with chancres. The results were reported in 1932 from data obtained in 1930. One patient made a prompt recovery, while secondary lesions developed in the other in spite of the fact that he had had ten fever treatments with rectal temperatures ranging between 39.7 and 40.8 C (103.5 and 105.5 F) for at least five hours during each treatment. At that time it was ascertained that the intra-urethral temperature of the male is at least 0.55 degree C (1 degree F) lower than the rectal temperature. The temperature of the mucosa of the glans, where the lesions were located, must therefore have been definitely below that supposed to be destructive to the spirochetes of the chancre.

Following these investigations, a third patient suffering from primary syphilis was treated with hyperpyrexia, and again prompt healing of the lesion was observed. Later secondary lesions developed but the rash was confined entirely to the face and scalp, the parts of the body that were uncovered during treatment. The local primary lesion again disappeared, but this did not prevent or materially influence generalized infection. Since syphilis is a systemic disease even in its primary stages, the local cooling of the skin of the face and scalp was believed to be the reason for this failure. In attempting to reconcile these first failures with the theoretical spirocheticidal temperature of 41 C (105.8 F) maintained for one or two hours, our conclusions were as follows. First, the temperature of various parts and organs of the human body varies and the surface of the glans of the penis is at least 1.1 degrees C (2 degrees F) lower than the rectal temperature. This relationship is maintained during fever produced by penetrating heat. Second, the temperature of the exposed surfaces of the skin, especially of the face and scalp, is too cool to be spirocheticidal at body temperatures, i. e. rectal temperatures ranging between 41 and 42 C (105.8 and 107.6 F), the upper limit of safe artificial fever treatment.

Three of our patients afflicted with primary and one patient with primary and secondary syphilis were therefore treated in an entirely different manner. The subject was placed in a hot air cabinet so constructed that he could be rolled in and out while in a horizontal recumbent position. The air temperature of this cabinet could be controlled with ease. A glass headpiece was fitted to the end of the cabinet in such a manner that the subject was bathed in hot air from toe to pate. Besides this diathermic electrodes were adjusted to his back and chest. Thus it was possible to apply varying amounts of external and penetrating heat at will. Furthermore skin temperatures were recorded by

means of thermocouples placed inside small needles which were inserted under the skin of the chest face and scalp. Thus it was possible to maintain at will a definite measured temperature throughout the patient's body. Needless to say this complicated procedure was attended with many technical difficulties but we believed that the possible accomplishment of our goal, the cure of syphilis in its earliest stages, justified our efforts.

We do not recommend this technic to any one. It is highly experimental. Placed in such an environment that the external temperature of the air he breathes is approximately 54.4 C (130 F) with about 65 per cent humidity, every patient reacts with a violent delirium, after the skin temperature has been maintained above 41 C (105.8 F) for an hour or even less. Nevertheless we were able, but only barely able, to maintain skin and rectal, that is to say the external and internal temperatures, at this level or slightly above it for two hours during each treatment. In other words, every part of the patient was actually heated above 41 C (105.8 F) during a two-hour interval.

With this technic one patient was given two treatments, one three treatments and two were given four

Fig 1 (case 1) —Primary lesion (A) before treatment and (B) after three hyperpyrexia treatments totaling twenty seven hours of temperature above 39.9 C (103.5 F) and for twelve hours above 41 C (105.8 F) of this total febrile period.

treatments. As before stated, the external and internal temperatures were kept well above 41 C (105.8 F) for at least two hours, supposedly the lethal temperature for spirochetes. These four patients were then closely observed in the hospital. One of them showed secondaries at the time of admission. These as well as the chancre, disappeared after the second treatment, to recur a week after the fourth and final treatment. The other two patients developed syphilitic rashes six and seven weeks after their final treatments, and the fourth patient developed a syphilitic pharyngitis two months after cessation of treatment. In other words, the syphilitic infection progressed in spite of now theoretically adequate heat treatment.

The inflamed lymph glands of these four patients decreased markedly in size but did not disappear entirely. In one case these glands later enlarged a second time, and finally a generalized adenopathy resulted. An epitroclear gland was removed and found to contain many spirochetes and pus. All chancres healed promptly and were always found to be superficially free from spirochetes twenty-four hours after treatment. No spirochetes were found in them at any

time after the second treatment, even when sectioned, impregnated with silver and stained. The Wassermann and Kahn reactions, positive in three cases before treatment was started, became more positive but remained negative in the other patient. Judging from these four cases, as well as the three cited previously, it is therefore safe to conclude that hyperpyrexia even when apparently applied in adequate doses and even when the external surface of the skin is heated to a spirocheticidal temperature, is not able to eradicate the syphilitic virus. However we believe that it is also safe to conclude that hyperpyrexia per se influences and partially arrests the progress of the disease.

A lymph gland from each of these four patients treated with hyperpyrexia alone was removed. These glands were sectioned and stained. Fragmented or normal appearing spirochetes were found in three of the glands despite the fact that the sectioned site of the chancre removed at the same time showed no organisms. This seemed very paradoxical until the latest researches of Bessemans, Van Haelst and De Wilde¹⁰ gave some insight into the true state of affairs. According to these investigators the spirochetes found in the

Fig. 2 (case 1)—Spirochetes in a histologic section of a chancre before treatment

inguinal and popliteal lymph glands of syphilitic rabbits and guinea-pigs and in the spleen and brain of syphilitic mice are organisms adapted to more difficult conditions of existence. They are very virulent, one single organism is capable of causing an infection, and they are quite resistant to heat and chemotherapy. In all these attributes they differ from the spirochetes found in primary and other active lesions. These facts definitely ascertained in animal syphilis may well apply to human syphilis. At least we believe they explain the seven failures cited. A similar failure was cited by Boak, Carpenter, Goldstein and Warren.¹¹

Epstein and Cohen¹² treated thirty-three cases of early syphilis with artificial fever ranging between 39 and 40.5 C (102.2 and 104.9 F) maintained for six or seven hours. They gave between two and four treatments in each case and observed that in thirty-one of these thirty-three cases the darkfield was rendered negative by means of hyperpyrexia alone and that the

clinical lesions of early syphilis healed promptly in all cases in which the darkfield examination became negative. The serologic reactions were not reversed from positive to negative in any case, and three clinical recurrences were observed after cessation of treatment. While the temperatures employed by Epstein and Cohen were not high enough or sustained long enough to be definitely spirocheticidal when compared with facts ascertained by *in vitro* and *in vivo* experiments their conclusions that hyperpyrexia alone is not a satisfactory treatment of early syphilis coincide with our own point of view.

Simpson¹³ treated six patients with early syphilis more intensively with fifty hours of sustained fever between 40.5 and 41.1 C (105 and 106 F). Two of these patients relapsed after fever therapy, while the Kahn and Kolmer serologic reactions became less positive in three and more positive in one. Therefore if we combine these experiences of Boak, Carpenter, Goldstein and Warren, of Epstein and Cohen, and finally of Simpson with our own seven cases, we must reiterate the conclusion that artificial fever will not eradicate the syphilitic virus or cure the disease at temperatures not fatal to the patient. The literature now consists of forty-seven cases treated by hyperpyrexia alone. This treatment has failed uniformly.

The next patient in the present series was treated with massive doses of arsphenamine and a bismuth compound immediately after the hyperpyrexia treatments were ended. The Wassermann and Kahn reactions, which had become positive, were reversed to negative one month later, and the patient has remained apparently free from all signs of syphilis during the past eighteen months. He has had no antisyphilitic treatment during this period.

A brief summary of the clinical history follows.

The patient was admitted to the hospital, March 5, 1934. Exposure had occurred six weeks before, and a lesion had been noticed in the sulcus of the penis twelve days before admission. On admission two lesions 2 by 3.5 cm, one on the shaft and one in the sulcus of the penis, were seen. They were definitely circumscribed, elevated, flat topped with saucer shaped erosions which were encrusted and had a serosanguineous discharge. There was an inflammatory areola around these lesions. The inguinal lymph glands were bilaterally enlarged, rubbery in feel and painless on pressure. The darkfield was positive. Wassermann and Kahn reactions were negative. A biopsy of the chancre showed many spirochetes.

The patient was given the first hyperpyrexia treatment March 5. External (skin) and internal (rectal) temperatures were maintained at approximately 41 C (105.8 F) for two and a quarter hours. After the treatment, no spirochetes were seen in the darkfield.

March 8 the Wassermann reaction was +++ and the Kahn reaction ++++. One atypical spirochete was seen in the darkfield and a great number of round and ovoid bodies were observed with curious flagella or whiplike appendages. The primary lesions were decreased to half their size and the right inguinal lymph glands were smaller.

The second hyperpyrexia treatment was given with external and internal temperatures above 41 C (105.8 F) for two and a quarter hours and above 42 C (107.6 F) for one hour.

March 12 the Wassermann reaction was +++ and the Kahn reaction ++++. Biopsy of the ring of the chancre, which was completely healed, showed no spirochetes. The chancre was epithelialized and only a very small ring from the biopsy remained at its former site. The regional lymph glands have further decreased in size.

The third hyperpyrexia treatment was given with external and internal temperatures above 41 C (105.8 F) for two and three quarter hours and above 42 C (107.6 F) for one and a half hours.

March 15 the Wassermann reaction and the Kahn reaction were +++

March 16 a gland the size of a cherry stone was removed from the left inguinal region. Spirochetes were found in microscopic stained sections of the gland. A transplant into a rabbit's testicle did not produce a syphiloma.

March 19 the inguinal lymph glands were no longer palpable. The site of the operative wounds healed. There were no secondaries.

March 22 the Wassermann reaction was +++ and the Kahn reaction ++++. Neosarsphenamine, 0.45 Gm., was administered.

March 24 bismuth salicylate, 1 grain (0.065 Gm.) was given.

March 28 neosarsphenamine 0.9 Gm. was administered.

March 31, bismuth salicylate 1 grain was given.

April 2 neosarsphenamine 0.9 Gm. was administered.

April 4, bismuth salicylate, 1 grain was given.

cent positive before treatment was begun. Possibly this is due to the sudden death of great numbers of spirochetes, the endotoxins of which are massively liberated and suffused into the body liquids. A further fact of great interest is the presence of spirochetes in microscopic sections of a lymph gland of the patient while the sections of the chancre or original site of infection show no organisms. It is also interesting to note that in this case the lymph gland which contained somewhat atypical appearing spirochetes, did not produce syphilomas when transplanted into rabbit testicles.

Buoyed up by this favorable result, we treated six further cases with combined heat and chemotherapy. The clinical results of these seven cases obtained with combined therapy are summarized in the accompanying

Clinical Results Obtained with Combined Therapy in Seven Cases

| Case | Name | Date Admitted for Treatment | Type of Syphilis | Reaction Before Treatment | Type of Treatment | Number of Days of Treatment | Maximum Reaction During Treatment | Maximum Reaction After Treatment | Clinical Results |
|------|--------|-----------------------------|-----------------------|--------------------------------------|--|-----------------------------|--------------------------------------|--|--|
| 1 | C S | March 5 1934 | Primary | Wassermann negative Kahn negative | Three sessions of hyperpyrexia followed by 4 injections of arsphenamine and 4 injections of bismuth salicylate | 46 | Wassermann +++ Kahn ++++ | Wassermann remains negative Kahn remains negative | No clinical sign of syphilis for 18 mos. after treatment ceased |
| 2 | R L | Oct 8 1934 | Primary | Wassermann negative Kahn ++ | Five sessions of hyperpyrexia with 0.3 Gm. of arsphenamine injected during last session followed by five injections of neosarsphenamine and three injections of bismuth salicylate | 63 | Wassermann ++++ Kahn ++++ | Wassermann remains negative Kahn remains negative | No clinical signs of syphilis 14 months after treatment ceased |
| 3 | R G | Oct 18 1934 | Primary and secondary | Wassermann ++++ Kahn ++++ | Eight sessions of hyperpyrexia followed by six neosarsphenamine injections and three injections of bismuth salicylate | 63 | Wassermann ++++ Kahn ++++ | Wassermann remains negative Kahn remains negative | No clinical signs of syphilis during 14 months since treatment has become negative |
| 4 | J P | Dec. 8 1934 | Early primary | Wassermann negative Kahn negative | Nine sessions of hyperpyrexia interspersed with four injections of neosarsphenamine | 30 | Wassermann negative Kahn negative | Wassermann remains negative Kahn remains negative | No clinical signs of syphilis during 13 months since treatment has become negative |
| 5 | J. McC | July 11 1935 | Primary | Wassermann negative Kahn negative | Three sessions of hyperpyrexia interspersed with and followed with five injections of neosarsphenamine | 18 | Wassermann ++++ Kahn ++++ | Wassermann remains negative Kahn remains negative | No clinical signs of syphilis for 7 months since treatment ceased |
| 6 | C Z. | July 24 1935 | Primary and secondary | Wassermann ++++ Kahn ++++ | Two sessions of hyperpyrexia with 0.3 and 0.4 Gm. of neosarsphenamine given at height of fever followed by 3 injections of bismuth salicylate | 43 | Wassermann ++++ Kahn ++++ | Wassermann remains negative Kahn remains negative | No clinical signs of syphilis for 6 months since treatment ceased |
| 7 | A. G | Sept 22 1935 | Primary and secondary | Wassermann ++++ Kahn ++++ | Three sessions of hyperpyrexia with 0.3 and twice 0.6 Gm. of neosarsphenamine given during these sessions followed by two injections of bismuth salicylate | 23 | Wassermann ++++ Kahn ++++ | Wassermann remains negative Kahn remains negative | No clinical signs of syphilis for 5 months since treatment ceased |

April 6 the Wassermann reaction was ++ and the Kahn reaction was ++.

April 11, neosarsphenamine, 0.9 Gm. was administered.

April 13, the Wassermann reaction was ++ and the Kahn reaction was ++.

April 18 bismuth salicylate, 1 grain, was given.

April 20 the Wassermann reaction was negative and the Kahn reaction was negative.

Following this the patient was given seven injections of neosarsphenamine and ten injections of bismuth salicylate up to Sept 6, 1934. The serologic reactions have remained consistently negative and the patient has shown no further signs of syphilis in the eighteen months since all treatment ceased. He has married and a healthy child has been born. The serologic reactions of the wife and child are negative.

Summarizing this case, we believe that the disease was apparently aborted in forty-six days by the use of combined treatment. It is interesting to note the immediate flare up of the Wassermann and Kahn reactions after the first session of hyperpyrexia. We have noted an increase in the intensity of the serologic tests in almost every case in which such tests were not 100 per

cent positive before treatment was begun. Possibly this is due to the sudden death of great numbers of spirochetes, the endotoxins of which are massively liberated and suffused into the body liquids. A further fact of great interest is the presence of spirochetes in microscopic sections of a lymph gland of the patient while the sections of the chancre or original site of infection show no organisms. It is also interesting to note that in this case the lymph gland which contained somewhat atypical appearing spirochetes, did not produce syphilomas when transplanted into rabbit testicles. Buoyed up by this favorable result, we treated six further cases with combined heat and chemotherapy. The clinical results of these seven cases obtained with combined therapy are summarized in the accompanying table. A survey of this table shows that in every case all symptoms of the disease disappeared shortly after combined therapy was instituted. These seven patients have remained free from all clinical and serologic symptoms for periods ranging from five to eighteen months. The seventh patient showed the usual absence of clinical symptoms after treatment, but the Wassermann and Kahn reactions were still four plus, Oct 8 1935. At this time he left the city against medical advice and could not be contacted again until February 1936. In the interim his serologic tests became negative without further treatment, and no clinical signs of syphilis were present when he was reexamined in February. In 100 per cent of this small series the results have therefore been excellent during the observation period of from five to eighteen months.

What occurred during treatment and in what manner were these results obtained? Four of the seven cases were primary, with negative or practically negative serologic reactions at the time of hospitalization. J P (patient 4) had a very early primary lesion, seven days

old with a moderate enlargement of the regional lymph glands. In this case the Wassermann and Kahn reactions remained negative. Figure 1 shows the primary lesion before treatment and ten days later after three hyperpyrexia treatments totaling twenty-seven hours of temperature above 39.9 C (103.5 F) and above 41 C (105.8 F) for twelve hours of the total febrile period. The action of heat alone on the clinical lesion

Fig. 3 (case 1).—Absence of all spirochetes in the histologic sections of the site of the chancre after two hyperpyrexia treatments. Temperature above 41 C (105.8 F) for four and one half hours and above 42 C (107.6 F) for one hour.

is apparent and typical. At this time the regional lymph glands had decreased in size but could still be palpated as hard, discrete nodules. Judging from our experiences with the first seven cases treated with heat alone, they would have served as foci of infection for the spread of the disease had treatment been discontinued at this point. After the first hyperpyrexia session, repeated darkfield examinations of the serosanguineous fluid obtained from the base of the chancre showed no spirochetes. This is also a typical finding true of all cases treated with this amount of artificial fever.

In the other three primary cases, consisting of case 1, the clinical history of which has already been summarized, and cases 2 and 5, positive or more intensely positive serologic reactions developed after the first fever treatment. This was also true of six of the seven cases treated with fever alone. It is therefore safe to conclude that there is a rapid and intense mobilization of antibodies following fever therapy. We theorize that this is due to a massive destruction of the spirochetes but realize that other factors may play an important role in bringing about this increase of antibody formation. Only the youngest chancres with the least systemic involvement treated by us did not show this immediate change to a more positive serologic reaction.

A biopsy of the chancre in case 1 showed many spirochetes. Figure 2 is the reproduction of a drawing made from a microscopic section of this biopsy. The second biopsy of the site of this chancre after two hyperpyrexia treatments (fig. 3) shows an absence of all spirochetes, a regression of the inflammatory processes and a decrease of the small cell infiltration. A section of an inguinal lymph gland removed four days later after a third session of hyperpyrexia (fig. 4) shows fragmented and intact spirochetes. Such sections are typical of the lymph glands of patients treated with fevers above 41 C (105.8 F) for two or more hours.

Figure 5 shows practically the same changes in a microscopic section of a lymph gland of one of the first seven cases treated with hyperpyrexia alone after three sessions of fever, in which the external and internal temperatures were kept above 41 C (105.8 F) for one hour and above 42 C (107.6 F) for an additional hour during each treatment. Figures 4 and 5 are both representative sections of syphilitic lymph glands after such intense fever treatment.

A biopsy was made of every chancre. All microscopic slides showed changes before and after treatment similar to those seen in figures 2 and 3. Spirochetes were never found in the stained, silver impregnated sections of chancres after two or three sessions of hyperpyrexia. Five lymph glands were removed after intensive fever treatment. All showed the presence of intact or fragmented spirochetes if fever alone was used as a therapeutic agent. We believe that all these microscopic sections clearly demonstrate the destruction of spirochetes by heat alone, particularly in the chancre. However, we must conclude that not all spirochetes, especially those found in the lymph glands, are destroyed by heat. This is even true in cases in which temperatures of 42 C (107.6 F) have been employed for several hours and to temperatures of 41 C (105.8 F) for ten or fifteen hours. The experiments that fix the *in vitro* death point of spirochetes at 41 C (105.8 F) maintained for two hours or 42 C (107.6 F) maintained for one hour, therefore, do not apply to spirochetes found *in vivo* in human beings. Furthermore, the experiments with rabbit syphilis which seemed to demonstrate the possibility of eradicating the disease by means of temperatures similar in intensity to those applied by us, do not apply to human syphilis.

Patients 1 and 3 were treated with arsphenamine and bismuth salicylate after hyperpyrexia. In case 1 it took 3.15 Gm of arsphenamine and 4 grams (0.26 Gm.) of bismuth salicylate to reverse the serologic reactions which had become positive. Later 5.4 Gm of neo-

Fig. 4 (case 1).—Fragmented and degenerated spirochetes in a histologic section of an inguinal lymph gland after three sessions of hyperpyrexia at temperatures above 41 C (105.8 F) for more than two hours and above 42 C (107.6 F) for approximately one hour during each session.

arsphenamine and 10 grams (0.65 Gm) of bismuth salicylate were given during the next four and a half months as a precautionary measure against a recurrence of the syphilitic infection which we believed to be under control. It took forty-three days of combined treatment to reverse the serologic reactions after Wassermann and Kahn reactions had become negative. In

case 3, with primary and secondary syphilis, six injections of neoarsphenamine totaling 3.15 Gm and four injections of bismuth salicylate totaling 8 grains (0.52 Gm) were necessary to produce a negative serologic reaction after eight sessions of hyperpyrexia. After this 9 Gm of neoarsphenamine and 38 grains (2.5 Gm) of bismuth salicylate were injected during the following five months as a precautionary measure. Sixty-three days of treatment was necessary to achieve negative serologic reactions. The examination of the spinal fluid of both patients was negative as regards cell count, globulin, Wassermann and colloidal gold reactions at the end of the treatment period.

As our work continued we gradually intensified the treatment by giving neoarsphenamine during the three and four day interims between bouts of fever. This was done in cases 4 and 5. Case 4 has already been partially analyzed. After the first three sessions of fever, which resulted in the healing of the primary lesion, three doses of 0.3 Gm, one of 0.45 Gm and three of 0.6 Gm of neoarsphenamine were given in the intervals between and following seven intensive sessions of hyperpyrexia. Thirty-six days was consumed in treatment. Patient 5 was given three sessions of hyperpyrexia interspersed and followed by five neoarsphenamine injections totaling 2.885 Gm. The first case has remained clinically and serologically negative while the second remains negative after the usual preliminary positive flare up of the serologic tests. Eighteen treatment days was necessary to achieve this result.

We had already experimented with the injection of neoarsphenamine during the height of fever in case 2. We now continued these attempts in cases 6 and 7 and have given up to 0.6 Gm of neoarsphenamine at temperatures of 41°C (105.8°F). It is our belief that the time necessary to achieve a negative serologic reaction is further reduced by this method. Both cases are now clinically and serologically free from all signs of syphilis and have remained free for almost six months. The early and speedy eradication of the disease by this method therefore, seems probable. Patient 6 had only one kidney when treatment was begun. A nephrectomy because of renal tuberculosis had been performed three years previously.

All cases were tested for renal and liver function before and after treatment. The laboratory tests disclosed no signs of liver or kidney involvement after this therapy. It is therefore our belief that neoarsphenamine may be given to robust patients between bouts of fever and at the height of the fever in doses up to 0.6 Gm without damage to the liver or kidneys. Electrocardiograms taken before and after treatment showed no change. Fever produced by electromagnetic induction even when extremely high temperatures are employed is therefore a harmless therapy. It is of course, assumed that this therapy is always under proper clinical control and supervision.

The average time consumed in this treatment was forty-two days. An average of five sessions of fever was given each patient and an average of five injections of neoarsphenamine was given during the treatment period. A small amount of bismuth salicylate was also used. We believe that this combined method of treatment can materially decrease the period of treatment of early syphilis. We believe that the hope of an eradication of the disease in its early stages is brought a step nearer. Furthermore we have shown that heat alone destroys human spirochetes *in vivo* but that there is a difference in their resistance to pyrotherapy dependent on the location in which they vegetate.

SUMMARY

1 Fourteen cases of early syphilis were treated with hyperpyrexia. This therapy was combined with neoarsphenamine and bismuth salicylate in half of this number.

2 All of the seven cases treated with hyperpyrexia alone developed further clinical or serologic signs of syphilis after treatment ceased.

3 All of the seven cases treated with combined therapy became serologically negative and showed no clinical signs of syphilis for periods ranging between five and eighteen months.

4 The average length of the treatment period necessary to obtain a negative serologic reaction can be materially shortened by using this combined therapy. In this series it averaged forty-two days.

5 Neoarsphenamine may be given to robust patients in doses of 0.6 Gm at temperatures of 41°C (105.8°F) if this temperature is produced by penetrating heat, i. e., electromagnetic induction.

Fig. 5—Fragmented and degenerated spirochetes after three sessions of hyperpyrexia. External (skin) temperatures and internal (rectal) temperatures were maintained above 41°C (105.8°F) for one hour and above 42°C (107.6°F) for an additional hour.

6 *Spirochaeta pallida* found in human syphilitic skin lesions is destroyed by temperatures of 41°C (105.8°F) maintained for two hours. The same organism found in human lymph glands is not destroyed by longer and higher temperatures ranging above 41°C (105.8°F) for five or more hours, and above 42°C (107.6°F) for one of these hours.

7 Such high temperatures alone, or when employed for treatment in conjunction with arsenicals and bismuth compounds, produce no demonstrable evidence of injury to heart, liver or kidney function, provided they are produced by penetrating heat, i. e., electromagnetic induction.

8 If external heat is used especially if the temperature of the entire skin is raised to the same high level equal to that of the internal organs, terrifying states of delirium and dyspnea result.

9 It is probable that the syphilitic virus can be eradicated from all parts of the human body by the simultaneous use of high fever, arsphenamine and bismuth compounds.

10 This entire therapy presupposes an organized expert medical and nursing staff trained in giving hyperpyrexia treatments and the hospitalization of the patient during twenty-four hours for each session of hyperpyrexia.

EPIPERICARDIAL FAT

ITS NONRECOGNITION A COMMON CAUSE OF ERROR
IN X-RAY MEASUREMENT OF HEART SIZE

SYLVESTER MCGINN, M.D.

AND

PAUL D. WHITE, M.D.

BOSTON

A very important part in the cardiovascular examination of a patient is accurately to determine the size of the heart. In particular, and justifiably, much reliance is placed on x-ray measurement of heart size, provided certain sources of error are recognized and taken into account. The commonest cause of error has been that of distortion of the heart shadow by magnification when the x-ray tube is too close to the heart; this error has been much reduced and largely discounted by obtaining films with the tube from 6 to 7 feet (2 meters) behind the chest, with the front of the chest pressed against the film. This error is thus almost universally avoided, except that it is not yet everywhere appreciated that even the teleroentgenographic ("6 or 7 foot" film) heart shadow is considerably larger than the accurate heart shadow projection or orthodiagram, a statement should always be made as to which method is employed to obtain the heart measurements. A second common cause of error is to fail to take into account the shape and position of the heart when making measurements—two hearts of exactly the same size will vary considerably in area as well as in diameters if one is vertically placed in the thorax with the diaphragm low and the other horizontally placed with the diaphragm high. This cause of error is becoming better recognized although still far too frequent. A third common source of error and one far too little recognized, even on occasion by roentgenologists themselves is the reason for the present note, namely, the presence of a triangle of epipericardial fat at the cardiac apex. Fortunately it is possible easily to avoid this error if one

Fig 1—Illustration showing epipericardial fat, taken from the original paper of Schwarz.¹

thinks of it, and furthermore the error does not enter into the measurement of heart size by the old and simple clinical method of palpating the maximal apex impulse which lies well within the apex of the fat triangle.

In many individuals a considerable amount of fat is attached to the outer side of the parietal pericardium and may therefore be called epipericardial fat (fig 1). The accumulation of this fat is greatest at the pericardial attachment to both the right and left leaves of the diaphragm. At postmortem examination, we have seen this fat to be as much as 4 cm in width lying lateral to the apex, 6 cm in thickness, and extending upward on the pericardium for 7 to 8 cm, gradually diminishing in thickness. The proximity of this fat to the heart borders frequently obscures the true margins of the heart as seen by x-rays and may make it extremely difficult to measure the heart without including the surrounding fat.

Fig 2—Teleroentgenograms (seven foot heart films) made from patient. A shows obliteration of both cardiophrenic angles due to epipericardial fat during quiet respiration. B is a harder film taken during full inspiration a few minutes later to demonstrate the contrast in position and density between the shadows of the heart and of the epipericardial fat. The arrow indicates the true left cardiac border.

Schwarz¹ in 1910 called attention to the shadow caused by fat at the apex of the heart in x-ray films of the chest, and since that time a few others interested primarily in roentgenology have made similar observations.² Although its occurrence is familiar to many of those who interpret x-ray films, the importance of the recognition of this epipericardial fat by internists and practitioners in general has never been emphasized as it should be.

True enlargement of the x-ray heart shadow should cause considerable concern, as it invariably means either organic heart disease or at least temporary cardiac dilatation or pericardial effusion. Not infrequently when the heart shadow is measured the epipericardial fat is also included and this error sometimes results in the false impression that cardiac enlargement exists; the transverse measurement of the "heart" shadow may exceed half the internal diameter of the chest, increasing abnormally the so-called cardiothoracic ratio, and the area of the cardiac shadow may also be considerably increased. The importance of such an error in the case of a person with a normal heart can hardly be exaggerated.

The size of the patient does not determine whether or not epipericardial fat is present, but the largest accumulations do exist in obese individuals. When such persons are encountered and the roentgenogram shows the heart to be horizontal in position, extreme care must be exercised in locating the points on the heart border to be measured. Not only must the apex and the left cardiac border be carefully scrutinized but also the right border, as fat tabs are often found also at the angle of the right leaf of the diaphragm and the pericardium.

Read before the New England Heart Association Oct 26 1935.

1 Schwarz, G. Ueber einen typischen Röntgenbefund am Herzen Fettelbiger und dessen anatomische Grundlage. Wien. klin. Wchnschr. 23: 1850 1910.

2 The latest special roentgenologic reference to the subject has been very recently published. Kautz, F. G. and Pinner, Max. Extrapericardial Fat Bodies. Am. J. Roentgenol. 35: 40 (Jan.) 1936.

When the pericardial diaphragmatic angle is not clearly outlined and especially if it is obtuse, one may be suspicious of the presence of epipericardial fat. Fluoroscopic examination, particularly when the Bucky diaphragm is used, will show two shadows, the denser one being the heart shadow and the lighter one the epipericardial fat shadow. The differences in density of these two shadows can be demonstrated on teleroentgenograms ("7 foot" chest films) when they are made to give maximum contrast with sufficient penetration. This is well brought out by taking two films of the same case, one that is "soft" and gives little or no contrast between heart and fat shadows and a second that is "hard" and penetrating, causing the fat shadow almost to disappear. The difference in shadows can be further emphasized by taking two films, one during ordinary quiet respiration and one in full inspiration as shown by the accompanying illustration. Figure 2A is a routine teleroentgenogram ("7 foot" heart film) taken during quiet breathing, it gives the impression of cardiac enlargement until one looks at figure 2B. The latter film of the same patient was made during full inspiration and with more penetrating rays to bring out the contrast in the position and the density of the heart shadow and of the triangular areas of fat at both cardiophrenic angles.

Fluoroscopic examination may give further assistance in distinguishing the triangular fat tab at the left cardiophrenic angle. It is sometimes possible to note the pulsation of the apex of the heart inside the left border of density and so within the fat shadow. Moreover, change in respiratory phase alters the position of the epipericardial fat in relation to the heart shadow. In deep inspiration the outer half of the diaphragm is displaced farther downward than is its mesial portion. The epipericardial fat is more lateral than is the cardiac apex, so that in full inspiration it may become more distinctly a separate lobule as it descends farther with the outer part of the diaphragm than does the cardiac apex with the more central portion of the diaphragm. This is easily made evident also in teleroentgenograms.

Fig. 3—Teleroentgenogram (seven foot heart films) made from patient Y. A taken during quiet breathing. Internal chest diameter 25 cm and transverse cardiac diameter 14 cm. B taken during inspiration a few minutes later to illustrate the difference in relative position of the heart and fat shadows. Internal chest diameter 27.5 cm and transverse cardiac diameter 12.5 cm. The edge of the fat shadow is 1.5 cm. beyond the cardiac apex.

When the shadows of the heart and of the epipericardial fat can be distinguished, the true outlines of the heart borders are easily located for accurate measurements of the size of the heart. In figure 3A is a routine teleroentgenogram made with the tube at a distance of 7 feet from the heart and taken during

quiet breathing. The heart is in a horizontal position and the left cardiophrenic angle is indistinct. The internal diameter of the chest is 25 cm and the transverse diameter of the heart 14 cm, giving the abnormal cardiothoracic ratio of 14/25, indicative of enlargement of the heart. The cardiac area is 112 cm as measured by a planimeter. Figure 3B is a "7 foot" heart film of the same patient but made in full inspiration. It will be noted that the triangular area of fat at the left cardiophrenic angle can be much more easily distinguished. It has moved downward with the descent of the diaphragm and has consequently changed its position with relationship to the cardiac apex. The edge of the fat shadow extends 1.5 cm, beyond the true cardiac border, and if included in the measurement would still give an abnormal cardiothoracic ratio, indicating cardiac enlargement, especially in this phase of respiration.

SUMMARY

The presence of epipericardial fat at the cardiophrenic angles and especially on the left side just beyond the cardiac apex may be a source of error in measuring the heart shadow on roentgenograms ("7 foot" heart films) and may be misinterpreted as cardiac enlargement. The importance of such an error is obvious.

Massachusetts General Hospital

GLOMUS TUMOR

REPORT OF A CASE

FRANK J. JIRKA, M.D.

AND

CARLO S. SCUDERI, M.D.

CHICAGO

Synonyms that have been used for glomus tumor are angioneuroma, angiosarcoma, Popoff¹ tumors, tumeur glomique, tumeur du glomus neuromyo-arteriel, subcutaneous painful tubercle, angiomyo-neurome, subcutaneous glomae tumor, angioma, perithelioma, false neuroma, glomangiomas and neuromyo-arterial glomus.

The glomus unit is a short cut between the arterial and the venous elements. In reality, a more descriptive term is angioneuroma, since besides the vascular elements it consists also of sympathetic nerve fibers interwoven with the finer vessels. It was first described by Hoyer,² but its histologic structure was made clear by Sucquet.³

The diameter of the glomus varies from 60 to 220 microns, the smaller ones being found in the nail beds.

The function of the glomus was worked out by Lewis and Pickering⁴ and by Grant and Bland,⁵ who demonstrated its importance in temperature regulation. They showed that the glomus served for the maintenance of the temperature of exposed parts and the regulation of loss of heat.

Clinically it is characterized by a bluish discoloration of the skin mounted on the top of a small cutaneous elevation. This area is very painful and, when irritated, produces a most excruciating radiation of pain up and down the extremity. More than 50 per cent of them,

that she is not as susceptible as before because she has not had a cold or other illness since that time. The peripheral blood picture is normal.

Gross Examination—The spleen weighed 450 Gm and measured 12 by 10 by 10 cm. Bulging into the hilus and converting most of its contour from the normal concave to a convex shape was a yellowish, stonelike mass covered only by scattered fibrous strands. Elsewhere the splenic capsule was intact, although over a portion of the lower pole irregularly shaped.

Fig. 1—Density, position and size of the calcified mass in the splenic area after ureteral catheterization and injection of opaque medium through left catheter.

whitish yellow plaques occurred. The main splenic artery and vein were not present but a branch of the former and a tributary of the latter lay in the persisting segment of the hilus near the upper pole. In order to examine the lesion it was necessary to resort to sawing. The mass so revealed proved to be quite discrete, 7.5 cm in diameter and in addition to projecting into the hilus had cupped out a bed in the splenic substance, leaving a triangular fragment of apparently normal tissue at the upper pole and only the capsule elsewhere (fig. 2). At the center of the mass was an irregularly outlined whitish hyaline core. Completely surrounding and filling in all the indentations of this zone was a peripheral layer of yellowish calcified material which however, gave way to a translucent cartilaginous-like substance at the lower pole. In the latter region were scattered brownish specks, occasional blood vessels, small segments of splenic parenchyma adjacent to the capsule and one spicule of calcium.

Microscopic Examination—Sections cut to include the central whitish and adjacent calcified foci showed scattered bits of splenic cells and sinusoidal walls, a fair number of erythrocytes and numerous collapsed or open but always empty arterioles. In the main, however, the parenchyma had been reduced to a hyaline state with nothing more than a faint shadow of the original pattern remaining. Calcium deposition without bony metaplasia had converted parts of the hyaline into a dense and formless matter interrupted by nothing more than clear vacuoles. The translucent lower pole exhibited the same basic change although hyaline degeneration was less pronounced and not infrequently reticulum cells, patent blood-filled sinusoids and remnants of splenic follicles could be made out. The latter were sometimes the seat of hyperemia and of fresh hemorrhages. The follicular arterioles although patent and devoid of subintimal hyaline thickening were for the most part empty. From this prevailing picture there were variations in the direc-

tion of complete hyalinization on the one hand to almost nothing on the other. Deposition of iron-containing pigment was seen. The only deviations from normal in sections cut from the upper pole were subintimal hyaline degeneration of the arterioles and the occurrence of a few eosinophilic polymorphic nuclei. The former is so frequent in the splenic arteries of healthy persons of middle age and beyond that no importance was attached to its presence here. The branch of the splenic artery supplying the upper pole was normal.

The pathologic diagnosis was massive hyaline degeneration and calcification of the spleen, apparently resulting from traumatic injury.

COMMENT

The clear cut history of an accident producing a contusion and accompanied by pain over the spleen area forces one to think seriously of traumatic injury as the cause of the splenic lesion herein described, but the mechanism of its production is a matter of speculation. The pathologic nature of the lesion is such that only a few causes are possible, namely, traumatic rupture of the spleen or its vessels, infarction, infection, or parasitic infestation.

In our experience trauma commonly leads to rupture at one or more points over either the convex or the hilar aspects of the spleen, or both. Usually such tears are transversely directed in relation to the long axis of the organ, often stellate, and affect both the capsule and the parenchyma. Some degree of hemoperitoneum is constant. While we have never encountered an example of such a rupture excepting in the fresh state, it is reasonable to assume that in the event of recovery without splenectomy the organ would be surrounded by a partially or

Fig. 2—View of the spleen after sagittal sectioning. The calcified hyaline mass protrudes into the hilus and over much of its extent is a covering of little more than splenic capsule. The brownish spots in the glassy lower pole are bits of persistent parenchyma. Capping the lesion is a little normal spleen.

wholly organized hematoma and bound to surrounding structures by fibrous bands. Blood pigment deposition, liquefaction or calcification of any unorganized blood would complete the picture. Obviously such a rupture did not take place in our subject for the spleen was free.

Although we have never seen such a thing in a large post mortem service which includes many traumatic deaths, one

must admit the possibility of rupture of the splenic pulp without tearing the capsule and without hemorrhage external to the organ itself. In the event of such an injury a rapidly formed and large hematoma might quickly destroy a portion of the parenchyma and later organize or calcify. Under such circumstances the tissue about the hemorrhage might reasonably be expected to suffer from malnutrition, slowly die and finally become more or less hyalinized, as was the case in our subject. Although admittedly not susceptible to proof, this concept is the best explanation that we can offer for the necrobiotic process present in the spleen.

Infarction, while mentioned is out of the question, for large anemic infarcts of the spleen invariably involve the capsule as well as the parenchyma, total cellular necrosis follows, the dead and entirely avascular area shrinks, a well defined blood pigmented fibrous zone appears between the living and the necrotic segments, and fibrous adhesions form over the surface. All these features are lacking in the case at hand.

With respect to infection, we are unaware of anything other than tuberculosis that could give a picture of this kind, and there is no histologic evidence of its existence. While echinococcus cysts may eventually die and calcify the outline of the chitinous membrane is always left behind to serve as a means of identification, and this too is lacking in our case.

PYELOGRAPHY OF THE SURGICALLY EXPOSED KIDNEY

HERMAN L. KRETSCHMER, M.D. AND FAYE H. SQUIRES, M.D.
CHICAGO

As a result of the accuracy of modern methods of renal diagnosis, exploratory operations on the kidney are rarely performed at the present time. However, in rare instances it may be impossible before operation to obtain all the diagnostic evidence that is desired so that at the operation additional information will be of great value in deciding for or against nephrectomy.

In a recent case a preoperative diagnosis of right renal tuberculosis was made without the benefit of ureteral catheterization or intravenous urography. It was impossible to catheterize the right ureter because of a stricture at the lower end, although two attempts were made. After failure to catheterize the ureter, two sets of intravenous pyelograms were made five days apart. They failed to visualize the right side whereas the left side gave normal results.

At the operation the exposed kidney appeared normal. There was questionable thickening of the ureter, and the question immediately arose as to whether or not the kidney should be removed.

It was decided to obtain a pyelogram of the surgically exposed kidney before proceeding with the nephrectomy. Ten cubic centimeters of diodrast was injected into the unopened pelvis and a roentgenogram was made. This showed some dilatation of the three major calices with a clubbing of the upper and lower calices, the minor calices being very indistinct. The minor calices, from the middle major calix, were destroyed and the medium filled a pocket which was irregular in outline in this region. The changes in this pyelogram resemble those of a tuberculous lesion. The tentative diagnosis of renal tuberculosis was verified and all doubt about the propriety of nephrectomy was removed.

Roentgen examination by fluoroscopy or film during or at the end of operation for kidney stones is routine procedure in all urologic clinics.

Although the necessity for making a pyelogram on the surgically exposed kidney does not arise very often, in rare instances, as in our case in which it confirmed the preoperative diagnosis of renal tuberculosis in spite of the fact that the kidney showed no external signs of tuberculosis, it may yield information that will aid the surgeon in deciding for or against nephrectomy.

REPORT OF CASE

M. E., a man, aged 25, a medical student, admitted to the Presbyterian Hospital, Feb. 19, 1936, complained of pain in the right upper quadrant of the abdomen and an infection of the upper respiratory tract.

The family history and previous illnesses were irrelevant. There was no history of venereal disease.

The patient had had a head cold for the past week, which had kept him in bed, but he had no fever. Three days before, he was suddenly seized with a dull aching pain in the right side of the abdomen both anteriorly and posteriorly. Twenty-four hours before admission to the hospital he had a dull ache in the scrotum, the pain was severe and he was obliged to take medicine to control the pain.

Physical examination was negative except for possible swelling in the upper right quadrant. Rectal examination gave negative results.

Examination of the urine revealed no albumin and no sugar. There were 67 leukocytes and 122 red blood cells per cubic centimeter. Many tubercle bacilli were present in the sediment.

Blood count revealed 4,720,000 red blood cells, 9,400 white blood cells, and 90 per cent hemoglobin.

Drawing of pyelogram made on the surgically exposed kidney

Roentgen examination showed evidence of healed tuberculosis of the lung. The genito-urinary tract was negative for stone.

Cystoscopic examination was negative. The catheter on the right side met an obstruction one inch above the bladder, beyond which it was impossible to advance it, no specimen of urine was obtained. The catheter on the left side passed all the way into the kidney pelvis, urine from the left side was sterile and free of pus, no tubercle bacilli were found. A second attempt to catheterize the right ureter met again the aforementioned obstruction.

Two sets of intravenous pyelograms were made on February 22 and February 26. The first set revealed a normal condition on the left side, there was no visualization on the right side. The second set showed again a normal condition on the left side and no evidence of filling on the right side.

A diagnosis of tuberculosis of the right kidney with a stricture at the vesical end of the ureter was made and operation was advised.

The patient was operated on under ethylene anesthesia, February 28. Because of the normal appearance of the surgically exposed kidney, the question was raised by the patient's physician as to the justification for nephrectomy—as previously mentioned in this paper. An intravenous pyelogram was made and a nephrectomy was done. The diagnosis of renal tuberculosis was verified.

Special Clinical Article

RECENT ADVANCES IN THE STUDY OF VIRUSES AND VIRAL DISEASES

CLINICAL LECTURE AT KANSAS CITY SESSION

THOMAS M RIVERS, M D
NEW YORK

The word virus means poison, and before the relation of bacteria, fungi, spirochetes and protozoa to disease was recognized it was customary to use it in a non-committal manner to designate the causative agents responsible for certain maladies. As the etiologic agent of one disease after another was discovered, the word virus was still used at times to indicate a known infectious agent, for instance, the expression virus of syphilis is equivalent to *Spirochaeta pallida*. In addition to this new usage, the word was still employed to designate unknown or undiscovered etiologic agents. In view of Koch's postulates, infectious agents that had not been seen and cultivated on lifeless laboratory mediums were considered to be undiscovered or unknown, in spite of the fact that investigators were able to experiment with some of them, e g, the viruses of cowpox and smallpox, and to use them for prophylactic purposes. Thus at one time most workers considered and a few still look on the viral diseases as a heterogeneous group in which all maladies of unknown etiology are placed. To the initiate, however, the term virus is as specific in its designation as is the word bacterium, and the expression *Virus variolae* or virus of smallpox is as definitive as is the expression *Bacillus typhosus* or bacillus of typhoid. Thus, infectious diseases are now divided into groups caused by bacteria, spirochetes, fungi, protozoa, Rickettsia and viruses, respectively, in addition there are those of unknown etiology.

The diseases of man that are known to be caused by or that are strongly suspected of being caused by viruses are measles, German measles, mumps, fever blisters, herpes zoster, varicella, smallpox, vaccinia, rabies, psittacosis, common colds, influenza, the St. Louis type of encephalitis, Japanese type B encephalitis, epidemic encephalitis or Economo's disease, lymphocytic choriomeningitis, poliomyelitis, lymphogranuloma inguinale, foot-and-mouth disease, Australian X disease, louping ill, Rift Valley fever, yellow fever, papataci fever, dengue fever, warts, and molluscum contagiosum. In addition to man, lower animals, insects, plants and even bacteria are subject to viral maladies. In fact, no form of life seems to be exempt from such diseases and, as one examines the list, it becomes obvious that a large number of devastating infections fall into the group. Naturally physicians are interested in these conditions, but a broader interest in them has developed because of the discussion of the nature of viruses which leads one into a consideration, often philosophical, of the nature of living material versus that of inanimate substances.

NATURE OF VIRUSES

It would be futile at this time to attempt a discussion of all the interesting activities in the field of viruses. Consequently, it seems best only to excite curiosity

with regard to the nature¹ of these active agents and then to consider briefly some of the most important recent discoveries in the field that have a direct bearing on the practice of medicine.

With the discovery that minute animals and plants in the form of protozoa, spirochetes, fungi and bacteria, instead of miasmas and the wrath of the gods, are responsible for certain infectious diseases, it became customary to assume that all infectious maladies arise through the action of such agents or their toxins. Even after it was demonstrated that many disease-producing agents are smaller than ordinary bacteria, most investigators still thought that such agents possess the characteristics of bacteria, differing from them only in respect to size. Indeed, for a long time a large part of the activities of investigators was directed toward the cultivation of them on lifeless mediums similar to those used for ordinary bacteria. However, from the time that it was shown that certain infectious agents pass through filters that hold back ordinary bacteria, a few independent thinkers have suggested that these small agents differ from the larger and better known ones, and an occasional worker has been bold enough to state that some viruses are not living organisms but inanimate substances capable of producing disease in one host after another not through autonomous multiplication but through their repeated fabrication in properly stimulated or injured host cells.

Such was the state of affairs until in 1915 and 1917, respectively, Twort and d'Herelle discovered the bacteriophage, whereupon investigators became fairly equally divided into two camps, one set believing the bacteriophage to be a minute living autonomous organism, the other looking on it as an inanimate substance formed by perverted bacteria capable of producing a similar perversion in other susceptible bacteria with which it comes in contact. Although the bacteriophage is not so important epidemiologically and therapeutically as it once was thought to be, its discovery stimulated interest in other viruses, which has resulted in the accumulation of many valuable facts.

Filters of porcelain or diatomaceous earth are useful for the separation of bacteria from viruses, but through the use of them, little or no definite knowledge of the size of viruses can be obtained. Elford appreciated this fact and recently devised a method of preparing collodion membranes with graded pore sizes of sufficient uniformity to be of value in the estimation of the magnitude of viruses. By means of them it has been shown that not all viruses are of the same magnitude, that the size of the infectious units of each virus is remarkably constant, that some viruses, e g, that of vaccinia, are relatively large, possessing diameters of from 125 to 175 millimicrons, and, finally, that other viruses, e g, those of foot-and-mouth disease and poliomyelitis, are very small and with diameters of from 8 to 15 millimicrons approximate the size of certain protein molecules.

The facts that no known virus has been cultivated in the absence of living susceptible cells and that some possess the order of magnitude exhibited by large molecules of protein have induced certain workers to view the host cells as the source of the viruses. The most suggestive work along this line is that of Stanley who

Read in the General Scientific Meetings at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 12, 1936.

2. Elford W J. *Proc Roy Soc., London*, B 106: 216 (1937).
112: 384 (1933). Baner J H and Hughes T P. *J Gen Physiol* 18: 143 (Nov) 1934.

recently reported³ that he is able regularly to obtain large amounts of crystalline protein from plants infected with tobacco mosaic virus and that this protein has the property of exciting mosaic disease in inoculated plants. He is inclined to believe that the virus with which he is working is not a living organism but an autocatalytic substance arising from the proteins of the plant as the result of infection.

Stanley's experiments are important and his interpretation of the results may be correct, but less obvious explanations should be considered also. For instance, his crystalline protein may not be the virus but a new pathologic protein, serologically specific for the infection, resulting from the activity of the virus on the host, while the apparent infectiousness of his protein may be accounted for on the basis of its being accompanied regularly by the virus, which, in view of its minute size, might well constitute such a small part of the material that its detection by chemical and serologic technics would be difficult or impossible. Indeed, Hughes⁴ has already brought evidence to show that pathologic proteins may arise from a host as the result of an infection and that such proteins may be antigenic in the host giving rise to them.

On the other hand, some viruses seem to be sufficiently large to represent minute living organisms. In infectious material from vaccinia, smallpox, fowl pox, psittacosis, canary pox and infectious ectromelia, numerous oval or round structures, spoken of as elementary bodies, are seen by means of ultraviolet photography or proper mordants and stains. Considerable amounts of the elementary bodies of vaccinia⁵ have been obtained in a state of relative purity, and a chemical analysis⁶ of them has shown that they are composed of water, protein, fat, carbohydrate and ash in quantities compatible with the idea that they are small organisms, provided each elementary body represents only a single infectious unit of the virus.

Sufficient has been said to indicate that no unanimity of opinion exists regarding the nature of viruses. At present three sets of ideas seem to cover the possibilities: (a) The extremely small viruses may be inanimate incitants of disease, (b) the medium sized viruses may represent primitive forms of life unfamiliar to us, (c) the large viruses may be micromicrobes or the midgets in the microbial world. To predicate that all viruses are identical in nature would at least be bold if not foolish.

THE ACTION OF VIRUSES

In order to study the effects of the activities of viruses and to control the diseases caused by them it is not essential to know their exact nature. If that were true, we would still be without vaccination against smallpox and rabies.

Although no virus has been cultivated on ordinary laboratory mediums, many of them have been induced to multiply in vitro in the presence of living susceptible cells, that is, in tissue cultures modified to suit the occasion. Cultures of viruses made in this manner are easy to handle and have yielded valuable information and products suitable for prophylaxis. For instance, it has been demonstrated that once a virus has entered a cell no amount of antiserum brought in contact with

the cell can injure the virus or hinder its activity." Such a phenomenon throws light on the clinical observations that the administration of convalescent or immune serum to an individual in whom the signs and symptoms of a virus disease are already manifest is without value.

It also appears that calf vaccine lymph, the oldest and best instrument of vaccination, can be improved on by vaccine virus cultivated in flasks in the presence of bits of viable chick embryo tissue suspended in Tyrode's solution⁷. This cultured vaccine virus is free from ordinary bacteria and can be administered intradermally to human beings, in whom it produces an immunity to standard calf lymph virus without the formation of disfiguring scars and without marked systemic reactions.

In spite of the fact that the exact nature of the virus of yellow fever is still unknown, Reed and his co-workers⁸ many years ago showed that the virus is in the blood of patients and that it is carried from one person to another by mosquitoes. Within recent years, considerable additional information regarding the malady has been obtained. Stokes, Bauer and Hudson⁹ transmitted it to monkeys. Then Theiler¹⁰ demonstrated that white mice are susceptible and that the repeated passage of the virus through this host alters its pathogenicity for the monkey and man. With this altered virus mixed with immune serum Sawyer and his co-workers¹¹ have developed a safe and effective vaccine for the prevention of yellow fever in man. Furthermore, recent reports state that yellow fever virus grown in vitro in the presence of certain viable tissues becomes altered in such a manner that it is possible to use it for prophylaxis¹² in human beings.

When it was found that mice are susceptible to yellow fever, a neutralization test was devised by Sawyer and his co-workers¹³ by which it is possible to ascertain whether a person has had the disease. By means of the test it has been demonstrated that yellow fever is or has been endemic in parts of the world that previously had been considered free from the malady¹⁴. Furthermore, Soper¹⁵ has definitely found that in South America yellow fever is not always an urban malady but may occur in jungles remote from urban centers in the absence of the accepted vector, the *stegomyia* mosquito. This jungle yellow fever presents new problems regarding the transmission and control of the disease and constitutes a constant menace to urban centers.

In 1918 a disease called swine influenza, or "hog flu," appeared in this country. Shope¹⁷ has conclusively demonstrated that the malady as it occurs in nature is not caused by a single infectious agent but by the synergistic action of swine influenza virus and a bacillus, *Haemophilus influenzae-suis*. Koch's postulates have induced most investigators to hold the idea that in order to demonstrate the etiologic significance of an infectious agent it is essential to produce experimentally the disease in question by means of pure cultures of that agent. This attitude implies that each infectious disease is caused by one infectious agent. In view of such an attitude the results of Dr. Shope's work take on an added significance, because they clearly indicate that at least one disease as seen in nature can be caused only by the combined action of two infectious agents, a virus and a bacterium. Thus, the inability in the past to discover the cause of certain infectious maladies still classified as diseases of unknown etiology may be due to the fact that workers have been influenced too profoundly by the dictum of Koch.

Following the work on swine influenza begun by Shope in 1931, three British workers, Smith, Andrewes and Laidlaw,¹⁸ succeeded in 1933 in infecting ferrets with a virus found in the nasopharyngeal washings of patients with a disease diagnosed as influenza. Without much difficulty these investigators were able by serial passages to propagate the active agent in this host. Francis¹⁹ in New York has obtained from patients with influenza in Puerto Rico, Philadelphia, New York and Alaska a virus similar to that described by the British workers. Subsequent experiments by Francis¹⁹ and the British workers²⁰ have shown that these viruses collected from widely separated epidemics are serologically identical and that patients without antibodies specific for the virus at the onset of the influenzal attacks develop them during convalescence. Francis,¹⁹ and Andrewes, Laidlaw and Smith²¹ simultaneously demonstrated that white mice are susceptible to the virus, provided a ferret-adapted strain is instilled into the nostrils while the animals are under ether anesthesia. As might be expected, this observation has greatly facilitated work on influenza.²² Although no one has cultivated the virus on ordinary mediums, Francis and Magill²³ have succeeded in obtaining a sustained multiplication of the agent in a medium consisting of bits of viable chick embryo tissue suspended in Tyrode's solution. Furthermore, when the cultured virus is injected subcutaneously into human volunteers with few or no demonstrable neutralizing antibodies, illness similar to influenza does not occur but antibodies specific for the virus promptly appear.²⁴

Swine influenza was unknown before 1918. In view of the fact that the suggestion²⁵ has been made that hogs contracted the malady from man during the pandemic of influenza in 1918, considerable study has been devoted to the relation of the two diseases, which has resulted in the demonstration that the swine virus and the human virus are immunologically related but not identical.²⁶ Furthermore, it has been shown that swine are susceptible to the virus recently isolated from man but that the disease caused by it, although similar in many respects, is not identical with that induced by the swine virus.²⁷ Consequently it is within the realm of possibility that the swine virus represents the pandemic strain of human influenzal virus adapted to hogs.

Kruse²⁸, Foster²⁹ and Olitsky and McCartney³⁰ showed that common colds in man may be caused by a filtrable agent obtained from the nasopharyngeal washings of patients with the disease. Dochez and his co-workers³¹ have amply confirmed these observations and have extended them by demonstrating that apes are susceptible and that the virus is capable of multiplication in a special medium containing viable chick embryo tissue. No one, however, has definitely shown that ferrets and mice are susceptible to the virus of common colds, and the method of its cultivation³ is radically different from that used for cultivation²³ of the influenzal virus previously mentioned. These facts are decidedly in favor of the idea that the two viruses are different, and in the future most investigators in this field will undoubtedly consider them dissimilar unless further work yields conclusive evidence to the contrary.

At this time it is advisable to point out that one should not conclude that all cases of infection clinically diagnosed as influenza are caused by a single virus, i. e., the one recently isolated by the British and American investigators, because the viruses of yellow fever³² and Rift Valley fever³³ a disease of sheep, not infrequently produce in man a malady clinically indistinguishable from influenza. Moreover, Dochez³⁴ has obtained from cases diagnosed as influenza an active agent that tends to produce common colds in inoculated human volunteers. Finally, from many individuals suffering from an infection diagnosed as influenza no virus has been recovered. Although within recent years tremendous strides have been made in the study of common colds and influenza, much work still remains to be done before many of the problems in this field will have been mastered.

Until a few years ago, virus diseases of the central nervous system of man were not considered very common, the recognized ones consisted of rabies, poliomyelitis, Australian X disease, and epidemic encephalitis, or Economo's disease. Although the viruses of rabies

and poliomyelitis are well known and their activities in experimental animals have been studied extensively, the etiologic agent of epidemic encephalitis is still unknown, and the disease is placed in the virus group only by analogy because of its clinical, epidemiologic and pathologic pictures. The virus of Australian X disease³⁶ produced infection in experimental animals but was lost before its relation to other and better known viruses was established. Within a relatively short period, four more viruses have been shown to attack the central nervous system of man, and at least one of them is capable of causing an epidemic disease.

Two physicians have died of an encephalitis induced by a virus carried by monkeys. This agent, recently discovered and now known as the B virus,³⁷ is said to be related to but not identical with the viruses of herpes simplex and pseudorabies.

Louping ill is a viral disease of sheep in Scotland and the northern part of England. A number of laboratory workers have become infected³⁸ accidentally, some of whom manifested rather severe signs and symptoms of encephalitis, with an increased number of cells in the spinal fluid. So far as is known, no human being has died of the malady.

During the summer of 1933, more than a thousand cases of encephalitis occurred in and around St. Louis. Although it was difficult to differentiate clinically individual cases of this outbreak from individual cases of epidemic encephalitis, or Economo's disease, the epidemic as a whole manifested characteristics distinctly different from those of outbreaks of the latter malady. Muckenfuss, Armstrong and McCordock³⁹ succeeded without much difficulty in transmitting the disease to monkeys, and Webster and his co-workers⁴⁰ readily established it in white mice. Once a suitable experimental animal had been found, it was relatively easy to demonstrate that the infectious agent responsible for the epidemic is a small virus possessing a diameter of from 20 to 30 millimicrons. Furthermore, by means of neutralization tests conducted in mice, it has been shown⁴¹ that individuals at the onset of the malady do not possess antibodies against the virus while they develop them during convalescence that patients recovered from or chronically ill of Economo's encephalitis do not possess neutralizing antibodies against the St. Louis virus, that the St. Louis type of encephalitis was in the United States before 1933, and, finally, that it is still endemic and not restricted to St. Louis and its immediate vicinity.

In Japan, a disease known as summer or type B encephalitis⁴² has been recognized for a number of years. Many physicians and investigators appreciate the fact that epidemics of it are distinctly different from those of Economo's (type A) encephalitis. Furthermore, the clinical, pathologic and epidemiologic

aspects of this disease are in many respects strikingly similar to those of the St. Louis malady. Whether similar or identical viruses are operative in the two diseases remains to be ascertained by future investigations.

While working with material from the epidemic encephalitis in St. Louis, Armstrong and Lillie⁴³ encountered a new virus in monkeys. A report of their observations, in which they designated the active agent as the virus of experimental lymphocytic choriomeningitis, appeared in August 1934. Early in 1935 Traub⁴⁴ reported that he had discovered the same virus in his stock of white mice. Shortly after Traub's communication appeared, Scott and I⁴⁵ recorded the fact that we had recovered the virus from the spinal fluids of two patients who presented the picture of a mild meningitis, that is, they had fever, headache, nausea, vomiting, nuchal rigidity, Kernig's sign and a decided increase in the number of cells, mainly lymphocytes, in the spinal fluid. The infection in the two patients just mentioned was not unique, because recently we have recovered the virus from the spinal fluids of two more individuals with a nonbacterial meningitis, also from the blood of one of the patients the virus was isolated. Moreover, Findlay⁴⁶ in England has recovered the virus from mice and from the spinal fluids of two human beings. All patients from whom the virus has been isolated have made good recoveries.

In 1925 Wallgren⁴⁷ described a clinical entity which he designated as acute aseptic meningitis. Since the cases from which the virus of lymphocytic choriomeningitis has been isolated satisfy the criteria established for the diagnosis of acute aseptic meningitis, certain workers⁴⁸ have suggested that the new virus is the etiologic agent responsible for most if not all of the cases placed in Wallgren's group. The results of the work in my laboratory,⁴⁵ however, clearly indicate that only a few such cases are caused by this virus and that they should not be classified as acute aseptic meningitis but as lymphocytic choriomeningitis. One immediately asks, "What about the other cases placed under the classification of acute aseptic meningitis?" An entirely satisfactory answer is not yet available, but it is safe to say that a few may represent cases of the meningeal form of encephalitis or nonparalytic poliomyelitis, while the remainder are induced by a virus or viruses not yet discovered. In this connection it should be kept in mind that a certain number of patients with mumps also develop a meningitis or a meningo-encephalitis presumably caused by the active agent inducing the parotitis which has been shown by Johnson and Goodpasture⁴⁹ to belong in the viral group.

That affairs regarding the diagnosis of viral diseases of the central nervous system should be in the state indicated by the remarks just made is understandable when the fact is taken into consideration that the nervous system is capable of responding to injury in a limited number of ways. Consequently, it is not sur-

prising that different viruses attacking the central nervous system cause diseases with clinical pictures so similar that a differential diagnosis is difficult or impossible by means of clinical observations alone. This not only is true of viral diseases but also holds in regard to bacterial maladies. For instance, without the microscope and methods of bacterial cultivation, it would still be impossible to differentiate one type of pyogenic meningitis from another with any degree of accuracy.

VACCINES AND SERUMS

Physicians probably would like to know whether there are safe and effective vaccines and immune serums for the prevention and cure, respectively, of viral diseases of the central nervous system of man. Except for vaccines against rabies, there are none that I⁶⁰ would administer to my patients.

Although the use of vaccines and serums at present offers little of value in the prevention and treatment of poliomyelitis, the results of work with agents of another nature seem to present hope that a method of controlling the disease eventually may be evolved. It is now believed that the virus of poliomyelitis enters the brain from the nasal mucous membranes by way of the olfactory nerve. With this idea in mind, a number of workers have conducted experiments with several viruses in more than one host in order to ascertain whether the entrance of a neurotropic virus into the central nervous system can be blocked by the application of simple chemical substances to the mucous membranes of the nose.

In 1934 Olitsky and Cox⁵¹ demonstrated that mice which had received a number of intranasal instillations of tannic acid were temporarily resistant to the action of equine encephalomyelitic virus placed in the nose. In 1935 Armstrong⁵² reported the results of experiments in which he found that a solution of sodium alum produced an effect similar to that of tannic acid, in that local applications of it protected mice subsequently inoculated intranasally with the virus of the St. Louis type of encephalitis. Then Armstrong and Harrison,⁵³ and Sabin, Olitsky and Cox⁵⁴ showed that monkeys following repeated intranasal spraying of alum were resistant to the virus of poliomyelitis implanted on the nasal mucous membranes. Finally, Armstrong and Harrison⁵⁵ and Schultz and Gebhardt⁵⁶ found that a dilute solution of trinitrophenol may be substituted for alum.

From the results of the work just described, one can predict with a degree of certainty that during the coming summer experiments will be made in the field in the hope that progress in the prevention of poliomyelitis in man will be achieved. Let me suggest, however, that this type of experiment should be conducted only by those who have had proper training.

In this discussion it has been necessary to omit mention of many interesting activities and newly discovered facts. The material presented was chosen with the thought that it would illustrate the ascendant ideas in the minds of investigators in the field of viruses and supply information of value in the practice of medicine.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

Nomenclature of Endocrine Principles II

THE PRESENT UNSETTLED STATE OF ENDOCRINOLOGIC NOMENCLATURE HAS BEEN THE CAUSE OF INCREASING CONFUSION IN RECENT YEARS. IN AN EFFORT TO REMEDY THIS DEPLORABLE SITUATION THE COUNCIL SOLICITED THE COOPERATION OF A NUMBER OF EXPERTS WHO HAVE MADE FUNDAMENTAL CONTRIBUTIONS TO OLANULAR PHYSIOLOGY. THIS GROUP, TERMED THE ADVISORY COMMITTEE ON THE NOMENCLATURE OF ENDOCRINE PRINCIPLES IS COMPOSED OF THE FOLLOWING: DR. EDWIN ALLEN WILLARD, M. ALLEN, J. B. COLLIP, G. W. CORNER, E. A. DOISY, E. T. ENGLE, H. M. EVANS, R. T. FRANK, F. L. HIRSH, F. C. KOCH, LEO LOEB, G. F. MARRIAN, C. R. MOORE, OSCAR RIDDLE, P. E. SMITH, AND C. W. TURNER. M. S. BIRKING, CORRESPONDING SECRETARY. ON THE RECOMMENDATION OF THIS COMMITTEE, THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT WHICH IS THE SECOND OF A SERIES (THE FIRST ON THE NOMENCLATURE OF THE CORPUS LUTEUM HORMONE APPEARED IN THE JOURNAL, MAY 23, 1936, PAGE 1808). IT IS ANTICIPATED THAT OTHER REPORTS OF RELATED TOPICS WILL BE PUBLISHED IN THE NEAR FUTURE.

THE COUNCIL DESIRES TO EXPRESS ITS SINCERE APPRECIATION TO THE MEMBERS OF THE ADVISORY COMMITTEE FOR THEIR WILLING COOPERATION.
 PAUL NICHOLAS LEECH, Secretary

THE NOMENCLATURE OF "MALE HORMONES"

The first successful preparations of male hormone were obtained by McGee¹ (1927) in the lipid fraction of extracts of bull testes. This crude extract was further refined by Gallagher and Koch² (1929, 1930, 1934, 1935), the extracts proved capable of inducing growth of the capon comb (McGee, Juhn and Domm,³ 1928) and preventing, or repairing, castration damage on the accessory reproductive organs of mammals (Moore and McGee,⁴ 1928, Moore and Gallagher,⁵ 1930, Moore, Hughes and Gallagher,⁶ 1930, Moore, Price and Gallagher,⁷ 1930, Vatna,⁸ 1930, Heller,⁹ 1932). The active principle has been referred to variously as "bull testis extract," "male hormone from testes," "comb-growth-promoting substance" and "the testicular (or testis) hormone."

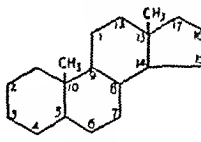

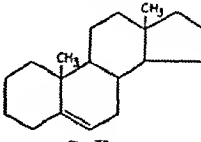

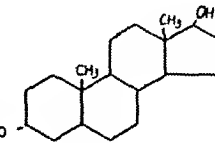

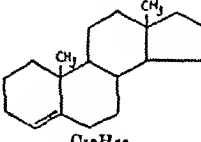

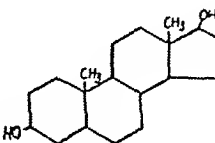

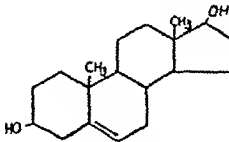

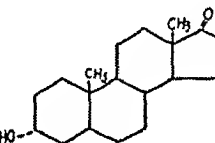

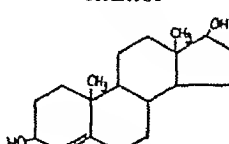

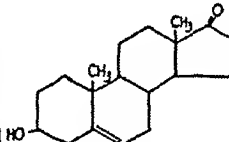

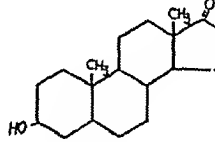

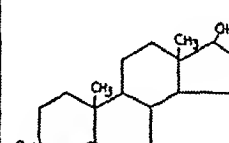

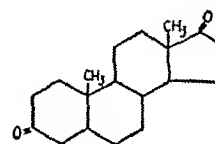

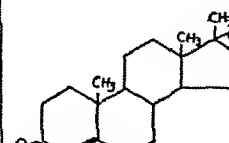

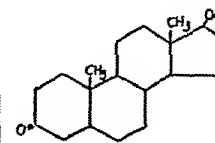

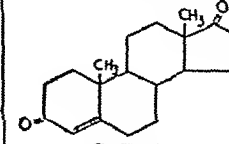

Loewe and Voss¹⁰ (1929) published accounts of extractions of testicular substance and the effects of resultant preparations on mammalian accessory reproductive organs. Their extracts were crude mixtures and the active principle was called "androkinin."

Funk and Harrow¹¹ (1929) obtained crude extracts of male urine that caused growth of the capon comb and designated the active principle in their products "the male hormone."

The active principle in extracts of urine has been studied in many other laboratories and has also been referred to as "male

* The chemical nomenclature in this table is given in two forms. The first is the one in almost exclusive use in the literature the second is in accord with the rule in the Definitive Report of the Commission on the Reform of the Nomenclature of Organic Chemistry (J Am Chem Soc. 55 3905 [Oct.] 1933) requiring that only the principal function be expressed in the suffix all others to be designated by appropriate prefixes. The latter method is the one employed in the chemical terminology of the closely related estrogenic compounds for consistency as well as conformity with the aforementioned international agreement. It should be adopted for the androgens as well.

It is obvious that such claims as these are unscientific and exaggerated. The public should be informed that gluten bread is not a proper source for obtaining elements to "build rich blood" or for adequate supplies of vitamins and mineral salts. Gluten bread was originally devised for a means of providing bread without starch. However, experience has shown that gluten bread has no place in the diet of the average diabetic patient.

As has been stated before by the Committee on Foods (THE JOURNAL, Nov 23, 1935) commercially prepared special diabetic foods are of little use to the diabetic patient. In general, the diet of the patient with diabetes should be exactly prescribed by a physician, who, in addition, has insulin at his command.

Furthermore, diabetic foods often run high in protein, which in some cases may be tolerated almost as poorly, if not quite as poorly, as starch in diabetes.

The Committee on Foods has declared, therefore, that Blubaugh's Genuine Gluten Bread is not acceptable for inclusion in the list of accepted foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary

- A 1 JUST RIGHT FLOUR (BLEACHED)
2 SAXONY CHOICE SOFT WHEAT FLOUR (BLEACHED)
3 SOUTHERN BELLE FLOUR (BLEACHED)
B 1 JUST RIGHT FLOUR PHOSPHATE ADDED (BLEACHED)
2 SAXONY CHOICE SOFT WHEAT FLOUR PHOSPHATE ADDED (BLEACHED)
3 SOUTHERN BELLE FLOUR PHOSPHATE ADDED (BLEACHED)
C 1 CHARMER SELF-RISING FLOUR (BLEACHED)
2 JUST RIGHT SELF-RISING FLOUR (BLEACHED)
3 SAXONY SELF-RISING FLOUR (BLEACHED)

Manufacturer—The Saxony Mills, Inc., St. Louis

Descriptions—A 1 Patent flour prepared from hard wheat, bleached. 2 and 3 Patent flour prepared from soft red winter wheat, bleached.

B 1 Patent flour prepared from hard wheat with 0.5 per cent of monocalcium acid phosphate, bleached. 2 and 3 Patent flour prepared from soft red winter wheat with 0.5 per cent of monocalcium acid phosphate, bleached.

C 1 2 and 3 Self-rising flour containing a patent flour of soft winter wheat (bleached), monocalcium acid phosphate, sodium bicarbonate and salt.

Manufacture—A Selected wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended, bleached with nitrogen trichloride (from 2.5 to 3.5 Gm per 196 pounds) and with a mixture of benzoyl peroxide and calcium phosphate (1 part to 50,000 parts of flour).

B Selected wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended, bleached with nitrogen trichloride (from 2.5 to 3.5 Gm per 196 pounds) and with a mixture of benzoyl peroxide and calcium phosphate (one part to 50,000 parts of flour) and finally mixed with 0.5 per cent monocalcium acid phosphate.

C The ingredients are mixed in definite proportions in a batch mixer and automatically sealed in paper and cotton sacks.

CELLU BRAND GREEN CUT ASPARAGUS, WATER PACKED

Distributor—Chicago Dietetic Supply House, Inc., Chicago
Packer—L. H. Schlecht, Rossville, Ill.

Description—Canned green cut asparagus packed in water.

Manufacture—Essentially the same as Cellu Brand Tips of Asparagus, Water Packed (THE JOURNAL, April 25, 1936, p 1473) except that tips are 1½ inches and stems cut in pieces of 1¼ inches.

Analysis (submitted by distributor) —

| | per cent |
|--|----------|
| Moisture | 95.1 |
| Total solids | 4.9 |
| Ash | 0.6 |
| Fat (ether extract) | 0.2 |
| Protein (N × 6.25) | 1.5 |
| Crude fiber | 0.7 |
| Starch (diastase method) | 1.7 |
| Carbohydrates other than crude fiber (by difference) | 1.9 |

Calories—0.2 per gram, 6 per ounce.

Claims of Manufacturer—Choice quality green cut asparagus packed without added sugar or salt. For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

STEPHENS BRAND ORANGE JUICE

Manufacturer—Natural Food Products Company, Orange, Calif.

Description—Canned California Valencia orange juice, retaining in high degree the original vitamin C content.

Manufacture—Same as Stephens Brand Grapefruit Juice (THE JOURNAL, May 16, 1936, p 1735).

Analysis (submitted by manufacturer) —

| | per cent |
|--|----------|
| Moisture | 86.4 |
| Total solids | 13.6 |
| Ash | 0.4 |
| Fat (ether extract) | 0.1 |
| Protein (N × 6.25) | 1.0 |
| Reducing sugars as invert sugar | 5.4 |
| Nonreducing sugars as sucrose | 4.3 |
| Crude fiber | 0.1 |
| Carbohydrates other than crude fiber (by difference) | 11.0 |
| Titratable acidity as citric acid | 1.0 |

Calories—0.5 per gram, 14 per ounce.

Vitamins—Chemical determination (iodine titration) of cevitic acid (ascorbic acid) shows 0.6 mg per cubic centimeter.

Claims of Manufacturer—Practically equivalent to fresh juice in vitamin C. For all table and dietary uses of fresh juice.

SANITARIUM BRAND WATER PACKED PINEAPPLE SLICED AND TID-BITS

Distributor—Battle Creek Food Company, Battle Creek, Mich.

Manufacturer—Hawaiian Pineapple Company, Limited, San Francisco.

Description—Peeled, cored and sliced Hawaiian pineapple, processed and packed in water, same as Dole Brand Hawaiian Pineapple, Water Packed, Sliced and Tid-bits (THE JOURNAL, March 14, 1936, p 923).

Claims of Manufacturer—Fancy grade canned sliced pineapple, representing fruit most uniform in color, flavor, texture and workmanship. Packed in water. The canned product is practically equivalent to the fresh fruit in nutritional values (vitamin C slightly reduced).

FAULTLESS BRAND TOMATO JUICE

Distributor—Nash-Finch Company, Pawhuska, Okla.

Manufacturer—Marshall Canning Company, Marshalltown, Iowa.

Description—Tomato juice seasoned with salt retaining in high degree the natural mineral and vitamin values. The same as Faultless Brand Tomato Juice (THE JOURNAL, April 4, 1936, p 1166).

BACTERIAL NOMENCLATURE

The confusion in classifications of "genera" and "species" of bacteria has not become materially less in recent years. Indeed, in the opinion of some bacteriologists, the multiplication of new generic names has made confusion worse confounded. The question of bacterial nomenclature will never be settled satisfactorily without some form of international agreement, and little progress has yet been made in this direction. Pending some general agreement by world bacteriologists it would seem desirable to maintain a conservative position, at least with regard to the hasty adoption of new names. Several instances are afforded in recent American practice. The term "Pfeifferella" as a bacterial genus including the glanders bacillus and certain related organisms was proposed some years ago but has not won general acceptance and has been abandoned in the fourth edition of Bergey's Manual of Determinative Bacteriology. A new genus "Listerella" is listed in the fourth edition of Bergey's Manual (1934) but this "genus" seems to have been established without any very extensive cooperative discussion. The sole organism described¹ in this genus, "L. monocytogenes," has apparently not been studied by any considerable number of bacteriologists with a view to determining its affinities and systematic position.

The precise status of Bergey's Manual as an arbiter of bacterial nomenclature has been frequently misunderstood and misinterpreted. Although the classification that it gives has been largely worked out with the aid of a committee of the Society of American Bacteriologists, the classification as a whole or in part has never been the subject of official action by the Society of American Bacteriologists and is not known to represent the matured opinion of even a majority of the members of the society. Although this fact has been frequently stated the nomenclature and classification laid down in the manual have been taken in many quarters to represent a usage recommended by the

society. It is not believed that it is the intention of the society to propose a definitive classification of bacteria irrespective of international usage and agreement.

For the time being it seems reasonable to hold that considerable effort should be directed toward diminishing rather than increasing multiplicity of names. The recent proposal of two experienced and well known American systematists² that the generic name *Bacterium* be retained as a temporary designation for non spore forming, rod shaped bacteria, whose relationships to other bacteria are not clear, will therefore be widely welcomed. For the present, as suggested by these writers, it is probably less confusing for those engaged in bacteriologic studies to use the terms *Bacterium coli*, *Bacterium aerogenes*, *Bacterium violaceum*, *Bacterium amylovorum*, *Bacterium zopfii*, *Bacterium monocytogenes* (not *Listerella monocytogenes*!), *Bacterium pneumoniae* and so on. In a word, until proper generic criteria and accepted names are established by international agreement, it seems wise to refrain from the hasty invention and use of new names. *Salmonella*, *Pasteurella* and *Brucella* have already won wide acceptance, but not *Pfeifferella*, *Listerella* and *Eschenchula*.

THE NEW AMERICAN MEDICAL DIRECTORY

The Fourteenth Edition of the American Medical Directory has been completed and copies are now available for general distribution.

The directory, with nearly twenty-five hundred pages, is a vast storehouse of information. It contains not only the most complete list available of the physicians of the United States and its dependencies and of Canada, but much additional data which hospitals, libraries and various other institutions, as well as individuals, will find useful and readily available. The directory is the only nation-wide register of physicians in which the extensive data on medical education, licensure and society affiliations have been verified.

The 1936 edition contains 183,312 names, or 4,796 more than were in the previous edition issued in 1934. The names of 13,157 physicians have been added and 7,684 names have been removed because of death. More than 70,000 changes of address have been made, in addition to thousands of changes in society affiliations, teaching positions, specialties and office hours.

In this edition, thirty-two states show an increase in the number of physicians, New York leads the list with 1,201, followed by California (369), Pennsylvania (281), New Jersey (262) and Massachusetts (249). A slight decrease in the number of physicians is shown in Missouri, Georgia, Kentucky, Tennessee, Oklahoma, Alabama, Indiana, South Dakota, Maine, Vermont, Mississippi and New Hampshire. When the thousands of changes of location are analyzed they seem to show a noticeable migration of physicians to

¹ Pirie J. H. II. Pub. S. African Inst. M. Research 3 163 (March) 1927.

² Breed R. S. and Conn H. J. J. Bact. 31: 517 (May) 1936.

he larger towns in the South Central states, a trend that was previously present also in some other sections of the country

The first section of 221 pages in the new directory includes the constitution and by-laws of the American Medical Association, the Principles of Medical Ethics, and a list of meeting places of the annual sessions of the Association since the first one in 1847, with the names of the President installed during each meeting. In this section also are lists of the hospitals that are approved for intern training, the medical libraries, the medical journals published in the United States, Canada, the Philippine Islands and Puerto Rico, the names of medical officers of the various government services, the national organizations for the various specialties with the names of their members, the membership of the new examining boards for the specialties, the medical schools in the United States and Canada with a brief history of each, and the members of the National Board of Medical Examiners.

The second section is arranged by states. There is published under each state the medical practice act, the members of the board of medical examiners, members of the state board of health, county and city health officers, and officers of the state, district and county medical societies. Following this is a list of 7,220 hospitals, sanatoriums and related institutions arranged by towns, with the name, location, bed capacity, superintendent, and type of patients treated in each institution. Then, arranged by towns, comes the great list of physicians, giving the year of birth, school, year of graduation and license to practice, membership in the state society and special societies, professorships, and Fellowship in the American Medical Association. The home and office addresses and office hours also are given for physicians in towns of more than 10,000 population.

A new feature in this edition is a key letter showing that a physician has been certified as a specialist by an approved examining board. Several of these boards have been approved by the Council on Medical Education and Hospitals since the directory went to press. The next edition therefore will contain a more complete list of certified specialists. An especially interesting feature of the 1936 edition is the list of American physicians temporarily located in foreign countries.

The third section, of 525 pages, is an alphabetical index of the names of 183,312 physicians, and practically every name is followed by the name of the city and state, thus indicating where in the directory detailed information about the individual physician may be found.

The bringing to completion of the Fourteenth Edition of the American Medical Directory has been a monumental task, in the pursuance of which thousands of individuals, societies, licensing boards, medical colleges and other organizations have cooperated. For their ready cooperation and assistance the American Medical Association is thankful and deeply appreciative.

MILK CONSTITUENTS AND THE EFFECTIVENESS OF VITAMIN D

As was pointed out recently in these columns,¹ milk has become increasingly popular during the last few years as a vehicle for vitamin D as "yeast milk," fortified milk or irradiated milk. Although there is still some question regarding the relative merits of these three forms, current agreement appears to favor the view that vitamin D milk in general is particularly effective as an antirachitic agent. Several explanations of its peculiar efficacy have been proposed: that different forms of vitamin D exist and that the predominating type in milk is especially effective, that the potency of vitamin D from animal origin exceeds that of the substance from plant origin, that the inherent calcium and phosphorus or the cholesterol content of milk is of primary importance.

Recently an attempt has been made² to ascertain the identity of the constituent or constituents of milk concerned in endowing this fluid with added antirachitic potency. Calcium and phosphorus were found to play no part, since the addition of these minerals in amounts consumed in milk to the vitamin D-supplemented ration produced no increase in antirachitic potency over that obtained with the vitamin-supplemented basal ration alone. Likewise, the fact that there is no parallelism between the fat content of milk and its antirachitic activity seemed to minimize the possibility that some lipid constituent of milk was involved. Thus there remained only certain constituents dissolved in or dispersed in the aqueous phase of milk for consideration. Since in earlier work³ the observation had been made that some lipid material bound as a prosthetic group to lactalbumin became antirachitically active when irradiated, a special study was made of the effect on the potency of vitamin D of dispersion in a colloidal suspension of purified lactalbumin. The results were rather striking. A definite increase in the antirachitic activity of "pure" vitamin D was observed following its dispersion in this medium. The increase in potency was particularly marked when specially prepared, lipid-free lactalbumin was employed. Further work seemed to indicate that some type of a firm union between the vitamin preparation and lactalbumin had occurred since, within limits, lactalbumin quantitatively retained all the vitamin D activity of the added material and since the retained antirachitic substance could not be removed by thorough washing. As would be expected, a similar enhancement in the antirachitic potency of vitamin D was obtained when a water-miscible solution of the vitamin was treated with skim milk or whole milk. However, there was little increase in the potency of an oily solution of the vitamin when treated with milk under comparable conditions.

1 Vitamin D Milk, editorial *J A M A* **106** 1664 (May 9) 1936

2 Supplee G C, Ansbacher S, Bender R C and Flanagan G E. The Influence of Milk Constituents on the Effectiveness of Vitamin D. *J Biol Chem* **114** 95 (May) 1936

3 Ansbacher S., and Supplee G C. The Cholesterol Content and the Antirachitic Activation of Milk Constituents *J Biol Chem* **105** 391 (May) 1934

The foregoing results were explained by assuming that vitamin D in aqueous solution reacts chemically with the secondary valencies of purified lactalbumin to form a "symplex," a system containing vitamin D as a lipid prosthetic group attached to the carrier, lactalbumin. The antirachitic potency of vitamin D present in this form is thus greater under the conditions of the experiment than that of uncombined vitamin D. The failure of an increase in antirachitic activity of an oily solution of vitamin D was attributed to the fact that the oil in which the vitamin was dissolved itself combined with some of the secondary valencies of the lactalbumin or perhaps other proteins of the milk, thus preventing the combination with the vitamin and the subsequent augmentation of its antirachitic activity. Although it is difficult to reconcile the foregoing hypothesis with certain other observations in the literature, particularly with the determination that practically all of the antirachitic potency of irradiated milk resides in the cream portion,⁴ the postulate that the peculiar effectiveness of vitamin D in milk is due in part at least to its combination and dispersion with lactalbumin merits further careful experimental study.

Current Comment

BLOOD PLATELETS AFTER SPLENECTOMY

One of the most striking and consistent hematologic changes that occur following the removal of the spleen is an increase in the number of platelets in the blood. This response has been observed both in normal persons in whom the spleen has been removed because of sudden rupture due to trauma and in splenectomized patients with certain diseases. Recently, further confirmatory data have been reported.¹ Splenectomy in three normal boys from 10 to 11 years of age was followed by thrombocytosis, the number of platelets increasing steadily to a maximum between the fifth and twelfth days, and decreasing slowly thereafter toward normal values. In one patient the platelet count increased from a normal level of 500,000 to a maximum of 1,640,000 on the twelfth day and then decreased, returning to the original value after some two months. Variations in the platelet counts of patients following splenectomy also were determined. Operation on twenty children with rheumatic disease was followed by an increase in the number of thrombocytes to values exceeding 1,000,000 in every case. As was found in the normal children, the peak of the rise occurred between the sixth and fourteenth days. A similar thrombocytosis was observed following operation in one case of splenomegaly of undetermined origin, in four cases of congenital hemolytic icterus and, with one exception, in eight cases of hemorrhagic thrombocytopenia. The results in the latter group are of particular interest because of the exceedingly low platelet counts

found in these patients prior to splenectomy. No consistent postoperative rise in platelets was found, however, in eight patients with Cooley's anemia. The degree of the increase in platelets was never as pronounced or as long in duration as those observed in the other conditions. No significant changes in the platelet count were found in control subjects in whom operations other than splenectomy had been performed. These observations add further to the evidence that the spleen is intimately related to the number of thrombocytes circulating in the blood stream. The nature of the regulatory action, however, is not known. Some investigators² have suggested that the spleen may act as a "death house" for platelets or may inhibit their formation and, therefore, that the thrombocytosis following splenectomy may be a result of a decreased thrombolysis or a decreased inhibition of platelet formation or, perhaps, both.

FEAR IN CHILDREN

Fear in children, like pain, according to Weber¹ is a danger signal called into existence to draw to the individual's notice the presence of some threat to his welfare. In its normal form, therefore, it is supposed to have ultimately a protective purpose, with a direct relation to self preservation. As an emergency reaction, however, its continued existence is probably harmful. The condition of body and mind to which it gives rise is injurious to the total well being of the organism. In view of the absolute helplessness of the new born infant, it is not surprising that at the outset of life fear plays little part. Since fear is a danger signal and hence implies some discrimination, this reaction is useless to the new-born infant, which is unable to discriminate. Rapidly, however, the infant is able to develop discrimination to some degree. Then fear becomes in many instances a powerful motivator of behavior. Within certain limits, anything that decreases the sense of security predisposes to fear. In this way a summation of factors may produce a state of terror. Fortunately for the child in whom this state has been produced, his powers of adaptation enable him to unlearn as well as to learn. Recognition of these fundamental facts is important from the point of view both of the physician and of the parent. It brings with it the realization that the child's fear is not cowardice or stupidity but is rather symptomatic of self preservation. A constructive view of such a situation and a more tolerant and understanding attitude of mind not only can lead to proper treatment of the fear but also strongly affects the relation between parent and child. The reaction is a specialized, not a universal, emergency reaction and some species of animals which lack this emotion have other means of defense at their disposal. The fact, however, that many animals also have this type of reaction suggests the possibility of deriving help from a comparative study. Thus many animals, as did primitive man, regard the unknown, often with justice, as a potent cause of fear. There is much reason to

¹ Wellstein, Martha, and Kreidel, Katherine V. Blood Picture After Splenectomy in Children with Special Reference to Platelets. *Am. J. Dis. Child.* 51: 765 (April) 1936.

² Krumbhaar, E. B. The Changes Produced in the Blood Picture by Removal of the Normal Mammalian Spleen. *Am. J. M. Sc.* 184: 215 (Aug.) 1932.

¹ Weber, Hilda. An Approach to the Problem of Fear in Children. *J. Ment. Sc.* 82: 136 (March) 1936.

believe that some of the fears of childhood represent an atavistic survival of this primitive dread. In any case, incorrect treatment of the fears of childhood often lays the foundation for much unhappiness and even illness in later life. A more satisfactory appreciation of the emotion opens the way to a more wisely tolerant and perceptive view of the frightened child's difficulties. Hence frequently childish doubts and dreads, which if neglected or mismanaged might be dangerous, become the starting point for intelligent management and real progress. Fears wisely dealt with early in life may in fact become a stimulus toward healthy mental development.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Outbreak of Poliomyelitis—Churches were closed in many north Alabama communities, July 12, as a precaution against the spread of an outbreak of infantile paralysis which has caused eight deaths, according to the *Chicago Tribune*. The number of cases was said to be 126, most of them confined to the upstate Tennessee valley counties and those adjoining.

ARKANSAS

Society News—The Washington County Medical Society was addressed June 2, by Drs. Arthur F. Hoge, Fort Smith, on "Surgery in Diabetes," and Leroy Long, Oklahoma City, "Prevention of Postoperative Intestinal Incompetence."—At a meeting of the Mississippi County Medical Society, June 2, Dr. Charles E. Wilson, Blytheville, spoke on "Mitral Insufficiency," and Dr. Thomas F. Hudson, Luxora, "Aortic Regurgitation."—Speakers before the Fifth Councilor District Medical Society in Magnolia, May 26, were Drs. George V. Lewis on "Ruptured Appendix," Silas C. Fulmer, "Treatment of Heart Disease," and Paul L. Mahoney, "Bronchoscopy," all are of Little Rock.—Drs. Lorenzo T. Evans, Batesville, and Paul H. Jeffery, Bethesda, discussed diabetes before the Independence County Medical Society at Batesville, June 8, and Dr. John J. Monfort, Batesville, "Anesthesia with Special Reference to Spinal Anesthesia."—Drs. George B. Fletcher and William T. Wootton, both of Hot Springs National Park, read papers before the Southeast Arkansas Medical Society at McGee, June 15, entitled "Under Water Treatment of Certain Types of Paralysis" and "Is There a Rheumatic Heart?" respectively.—The Eighth Councilor District Medical Society was addressed in Pettit Jean State Park, Morrilton, recently among others, by Dr. Augustus C. Shupp, Little Rock, on "Surgical Treatment of Tuberculosis."

CALIFORNIA

Dr. Porter Becomes Emeritus Professor—Dr. Langley Porter, who has retired as dean of the University of California Medical School, San Francisco, will continue his affiliation with the school 'in an emeritus position as an adviser in administration and research, according to the *San Francisco Chronicle*. For three years before he became dean and professor of medicine in 1927, Dr. Porter was in Rome, studying chiefly scarlet fever and translating works on that subject. Dr. Porter is 66 years old. He has been associated with the University of California since 1918.

Personal—Dr. John C. Decker, Portola, has been appointed health officer of Plumas County, succeeding Dr. Wilbur C. Batson, Greenville.—Dr. William Dock, associate professor of medicine, Stanford University School of Medicine, San Francisco, has been appointed secretary of the San Francisco Heart Committee to succeed Dr. Amos Christie, who has resigned to engage in a two year study at Johns Hopkins University Hospital for the U. S. Children's Bureau.—Dr. Richard D. Husband has been appointed superintendent of Stanislaus County Hospital, Modesto, succeeding the late Mr. Jay A. Rydberg.

CONNECTICUT

Society News—At a meeting of the Litchfield County Public Health Association in Canaan June 1, Dr. Stanley H. Osborn, Hartford, state health commissioner, discussed "Physicians and the Social Security Act," and Dr. Millard Knowlton, Hartford, "Streptococcus Sore Throat and Scarlet Fever."—At a recent meeting of the Yale Medical Society in New Haven, papers were presented by Dr. Robert M. Lewis on "Estrin in the Treatment of Gonorrheal Vaginitis," Daniel Melnick, Ph.D., "Effect of Diet on the Regeneration of Scrum Protein," Dr. Harry M. Zimmerman, George R. Cowgill, Ph.D., James C. Fox Jr. and Marion E. Howard, "Vitamin B₂ Deficiency in Dogs," and Dr. Henry G. Barbour, Jane Trace, B.A., and Paul K. Smith, Ph.D., "Observations on the Effects and Fate of Heavy Water in Mice."

DISTRICT OF COLUMBIA

Society News—Merle A. Tuve, Ph.D., Carnegie Institution department of terrestrial magnetism, Lyman J. Briggs, Ph.D., and Lauriston S. Taylor, A.B., U. S. Bureau of Standards, Dr. George W. McCoy, National Institute of Health, Dr. Edwin A. McRitt and Dr. William J. Mallory, professor of medicine, George Washington University School of Medicine, presented the scientific program of the meeting June 9, of the Academy of Medicine of Washington, D. C., which was organized April 28 (*THE JOURNAL*, June 6 p. 2011). The subject of discussion was "High Energy Particles and Radiations."

FLORIDA

New Bureau of Maternal and Child Health—The establishment of a bureau of maternal and child health in the Florida State Department of Health, Jacksonville, has been announced. Dr. Emile Bryant Woods, assistant professor of obstetrics and gynecology, University of Georgia School of Medicine, Augusta, has been named director. The new bureau will act in an advisory capacity to city, county and district health departments and will sponsor a statewide educational program. It was made possible through funds provided under the Social Security Act.

GEORGIA

Dr Lloyd D Felton, Baltimore Recent Incidence of Epidemic Meningitis
Dr Albert S McCown, Washington Maternal and Child Health in Relation to the Social Security Act

MASSACHUSETTS

Hospital News—During 1935 the Boston Dispensary recorded 130,578 visits to its morning clinics, 68.8 per cent of which were free. In the evening pay clinics for working people of small means, 27,372 visits were recorded, 13.6 per cent of which were free. The diagnostic hospital for clinic and private patients reported 4,797 days' care, 74.6 per cent of which was free, while physicians' visits to homes, free to those unable to pay, totaled 31,527

Mental Hygiene Survey—The Massachusetts Society of Mental Hygiene recently completed a survey of Springfield to determine the need for better mental hygiene facilities for the city and its suburbs More than thirty agencies were studied in addition to the school department and the local divisions of state agencies A report of the survey states that one of the most pressing needs is the training of staff personnel in mental hygiene to enable them better to detect personality and conduct disorders It recommends that psychiatrically trained personnel be included in the staff organization It recommends further that provision be made for additional clinical service for the public school system The report states that the present child guidance clinic at the Springfield Hospital, now operating on a part time basis, should be placed on a full time schedule to give service to both adults and children, and, in addition, extend its activities in the district court to include therapy to selected persons at the clinic The need for continued education of the public is emphasized

MICHIGAN

Hospital News—The second annual convention of the Intern Alumni Association of Providence Hospital Detroit was held at the hospital, June 10-11 Speakers included Drs Francis D Murphy, Milwaukee, on "Significance of Benign and Malignant Hypertension", Max M Peet, Ann Arbor, "Hypertension and Treatment," and Waltman Walters, Rochester, Minn, "Gastric Surgery" Frank Cody, superintendent of Detroit public schools, gave the banquet address

Commission on Welfare and Relief—Governor Frank D. Fitzgerald recently appointed a special commission on welfare and relief, composed of nineteen members. Physicians on the commission include Drs. Charles D. Pullen, Mount Pleasant, Donald M. Morrill, Grand Rapids, and Stanley W. Insley, Detroit, who is the representative of the Michigan State Medical Society. At a meeting with representatives of the state medical society in March, the governor proposed the organization of this commission to outline legislation designed to revamp and coordinate all state relief agencies (THE JOURNAL, May 2, p. 1576).

Grant for Research in Pneumonia Control—The Commonwealth Fund of New York has approved an annual grant of \$16,800 to the Michigan State Department of Health, Lansing, to promote study of antipneumococcus serum production. The fund's grant will be supplemented by an annual state appropriation of \$10,000. The objective of the study is to improve the antipneumococcus serum and to reduce the cost so as to make it available to the person of ordinary means. It will continue three years or longer, if sufficient progress is shown. Five persons will be added to the laboratory staff of the department, and \$2,000 will be available for the purchase of animals. Last year the death rate from pneumonia in Michigan was the highest since 1929.

MINNESOTA

Thirty-Three Years on Health Board—Dr. James F. Lynn resigned as president of the board of health of Waseca, April 14. He was first elected in 1901 and served continuously until the day he resigned, except for the years 1918, when he was in the World War, and 1910, when Dr. Alexander J. Rudolf, now of Milwaukee, held the position. Dr. Lynn graduated from the University College of Medicine, Richmond, in 1896, he is 65 years of age.

Regional Training Center—The University of Minnesota School of Medicine, Minneapolis, has been selected as one of the regional training centers in public health to be subsidized in part by the U. S. Public Health Service out of funds appropriated by the Social Security Act. An introductory course will begin September 28, to continue for three months. The first introductory course was attended by fifty-seven persons. The program is a cooperative one between the university and the state department of health with the added assistance of the local health departments and health agencies of the state. Dr. Harold S. Diehl, dean of the medical school, announces that graduate work on an individual basis may be undertaken at any time.

MISSISSIPPI

Personal—Dr. Jesse E. Brumfield, Tylertown, has been appointed head of the State Colony for the Feeble-minded at Ellisville, succeeding Dr. Romeo R. Halfacre.

Conferences of Local and County Registrars—The second annual conference of the county and district registrars was held at New Albany, May 28. Dr. John Collinson Jr., assistant chief statistician of vital statistics for the bureau of census, Washington, D. C., attended the meeting. Similar conferences were held at Laurel June 2 and Cleveland June 5.

MISSOURI

Refresher Courses—The Missouri State Board of Health will conduct refresher courses in obstetrics and pediatrics beginning this month. A portion of the funds available for maternal and child welfare work under the social security act has been set aside to make these courses available to physicians in rural areas without enrolment or tuition. Dr. Paul F. Fletcher, St. Louis, has been named to conduct the obstetric courses and Dr. Oscar F. Bradford, Kansas City, the pediatric courses. Motion pictures and lantern slides will be used with most of the lectures, followed by informal discussions. Clinical demonstrations will also be held whenever possible. The state has been divided into six districts, each lecture district comprising the counties in about five councilor districts. Each course will consist of eight lectures, one each week in a councilor district on the same day of each week, permitting the lecturer to give the same lecture in five councilor districts each week until the course is complete. The first course in obstetrics will be inaugurated in lecture district D, while the first course in pediatrics will begin in district A. It is expected to devote a full year to presenting these two courses to all counties in the rural areas.

Dr. Leo Loeb to Retire—Dr. Leo Loeb, Edward Mallinckrodt professor of pathology, Washington University School of Medicine, St. Louis, has announced his retirement to be

effective at the end of this year, newspapers report. Dr. Loeb, who is 66 years of age, graduated from the University of Zurich Faculty of Medicine in 1898. He has served at McGill University, the University of Illinois, New York State Pathological Laboratory, Buffalo, and the University of Pennsylvania. He was director of the department of pathology of the Barnard Skin and Cancer Hospital, St. Louis, from 1910 to 1915, serving as professor of comparative pathology at Washington from 1915 to 1924. In the latter year he became professor of pathology. From 1910 to 1912 he was chairman of the Section on Pathology and Physiology of the American Medical Association. He is a member of many scientific societies and was president of the American Association of Pathologists in 1914 and the Society of Cancer Research in 1911. Dr. Loeb's research has included, among other subjects, tissue and tumor growth, physiology of generative organs, pathology of circulation, venom of Heloderma, and analysis of experimental amoebocyte tissue. The Mu chapter of the Phi Beta Pi Medical Fraternity established a lectureship in his honor early this year. The first lecture was delivered by Dr. Walter B. Cannon, George Higginson professor of physiology, Harvard Medical School, Boston. In 1935 Dr. Loeb was awarded the John Phillips Memorial Medal by the American College of Physicians.

NEBRASKA

Personal—Dr. Edward R. Stewart, Blair, was honored at a meeting of the Burt, Washington and Dodge Counties Medical Society, Tekamah, May 26, for his completion of fifty years of medical practice.—Dr. and Mrs. Carroll D. Evans Sr., Columbus, celebrated their golden wedding anniversary May 27.—Dr. Frederick J. Schwertley, Omaha, was recently graduated from the Creighton Law School.—Dr. Floyd H. Kinyoun was recently appointed health officer of Omaha to succeed Dr. Millard Langfield.—The Wahoo Chamber of Commerce sponsored a dinner June 18 in honor of Drs. Charles F. Kirkpatrick, Ashland, and Andrew E. Stuart, Cedar Bluffs, who have practiced fifty years in Saunders County. Drs. George W. Covey, Lincoln, and Donald J. Wilson, Omaha, and Mr. H. E. Kokjer, Wahoo, were speakers.

Society News—Speakers who addressed the Madison-Six County Medical Society at a meeting in Wausa, May 26, were Drs. Joseph E. Dvorak, on "Eye Changes in General Disease"; Ronald F. Martin, "Therapy in the Toxemias of Pregnancy"; and Archibald F. O'Donoghue, "Injuries to the Spine." All are of Sioux City, Iowa.—Dr. John C. Thompson, Lincoln, addressed the Southwestern Nebraska Medical Society, May 24, at Indianola on anemia.—A symposium on fever therapy was presented before the Sixth Councilor District Medical Society, York, May 25, by Drs. Abram E. Bennett, Eugene E. Simmons and Charles A. Owens Jr., all of Omaha.—At a meeting of the Tenth Councilor District Medical Society, Ingleside, May 28, speakers were Drs. Adolph Sachs, Omaha, on "Diabetes"; George W. Covey, Lincoln, "Coronary Occlusion. Some New Thoughts on Restoration of Blood Supply to the Infarcted Heart," and Philip H. Bartholomew, Lincoln, "Public Health Work and the Maternal and Child Health Program in Nebraska."

NEW JERSEY

Dr. Shope Receives Award—Dr. Richard E. Shope of the staff of the Princeton laboratory of the Rockefeller Institute for Medical Research received a prize of \$1,000 awarded by Sigma Xi on the occasion of its semicentennial in June. An observance of the anniversary was held at Cornell University, Ithaca, N. Y., where the scientific honor society was founded, during the annual meeting of the American Association for the Advancement of Science. Dr. Shope is a native of Iowa and a graduate of the State University of Iowa College of Medicine, class of 1924. He joined the Rockefeller Institute in 1925. The Sigma Xi award was in recognition of Dr. Shope's work on swine influenza.

NEW YORK

Hospital News—The White Plains Hospital, White Plains, has recently opened a new service for treatment of cancer in affiliation with Memorial Hospital, New York. A tumor clinic will be established under supervision of Memorial Hospital, the staff of which is to act in an advisory and consultant capacity.

was painted by Leopold Seyffert, New York.—Dr Dayton L. Kathan, Schenectady, was guest of honor at the semiannual meeting of the Schenectady County Medical Society, June 4, in compliment to his completion of fifty years of practice.

Appointments to State Health Department—Dr Wildridge C. Thompson Jr., who recently received the certificate in public health at Johns Hopkins University, has been appointed full time medical consultant in social hygiene in the New York State Department of Health. Dr Helen H. Owen, Albany, has been provisionally appointed assistant director of the division of maternity, infancy and child hygiene. She was formerly on the staff of the division of laboratories and research. Dr Frank W. Laidlaw, Middletown, formerly a district state health officer, has been provisionally made district health director.

Society News—Dr Carl E. Badgley, Ann Arbor, Mich., addressed the Niagara County Medical Society, Niagara Falls, June 9 on "Common Fractures Met in General Practice."—Dr Ellery G. Allen, Syracuse, addressed the quarterly meeting of the Ontario County Medical Society, in Geneva, July 14, on "Recent Advances in Hematology."—Dr Orren D. Chapman, Syracuse, was elected president of the New York State Association of Public Health Laboratories at the annual meeting in May, and Mary B. Kirkbride, Sc D Albany, reelected secretary.—Dr Richard W. Weiser, Kenmore, was elected president of the New York State Association of School Physicians at the annual meeting in Saratoga Springs, June 22-23.—Dr Floyd Burrows, Syracuse, addressed the Medical Society of the County of Montgomery at its semiannual meeting in Amsterdam in June on collection methods.

New York City

Hospital News—Dr Leon Asher, professor of physiology, University of Berne, Switzerland, gave a lecture at Mount Sinai Hospital, June 11 on "The Thyroid Gland and the Central Nervous System."—Natale Colosi, Ph D, has been appointed general director of the Parkway Hospital.

Memorial Playground—A playground on Seventeenth Street west of Eighth Avenue, known as the Model Playground was recently dedicated and renamed the Dr Gertrude B. Kelly Playground in memory of Dr Kelly, who died in 1934. Mayor La Guardia spoke and a plaque commemorating Dr Kelly, was unveiled by Miss Dorothea Marty, a nurse from the New York Infirmary for Women and Children, with which Dr Kelly was associated for many years.

Gifts to Columbia—The following gifts to Columbia University for medical purposes were recently announced:

- The John and Mary R. Markle Foundation \$5 000 for research in brain tumors in the department of neurology
- The Chemical Foundation \$2 500 to establish a fund for research in brain chemistry
- Trustees of the Anna Fuller Fund \$1 500 for special research in the Institute of Cancer Research.
- Mrs. M. Maxim Steinhach \$300 for the Friedman Tuberculosis Fund in the department of bacteriology
- National Tuberculosis Association \$260 for research in tuberculosis

Report of Library—The library of the Medical Society of the County of Kings reports that in 1935 15 957 readers consulted 67 909 books in the library and took out 13 099 for home use. The first figure was an increase of 12.6 per cent over 1934 the second 9.03 per cent and the third 23.3 per cent. The library added 778 books to its shelves during the year by purchase and gifts. It has on file 1 524 serial publications, 882 in English and 642 in twenty-five other languages. Dr Jacques C. Rushmore is directing librarian and Mr Charles Frankenberger librarian.

Advisers on Hospital Service—The board of directors of the Associated Hospital Service of New York has appointed a group of physicians representing various branches of medicine to serve in an advisory capacity, especially regarding the eligibility of subscribers to services under the hospital plan. They are Drs Conrad Berens for ophthalmology, George W. Kosmak, obstetrics, Adolph G. G. de Sanctis, pediatrics, Matthew Shapiro, internal medicine, Clarence G. Bandler, urology, George A. Blakeslee, neurology, Samuel J. Kopetzky, otolaryngology, Edward J. Davin, gynecology, William Hadden Irish, orthopedics, Rupert Franklin Carter, surgery, Abernethy Benson Cannon, dermatology, and William H. Stewart, radiology.

OHIO

Campaign on Diabetes—The Public Health Federation of Cincinnati has recently formed a special committee on diabetes in cooperation with the Academy of Medicine of Cincinnati with Dr Cecil Striker as chairman. The committee plans to establish an information bureau for physicians and the public

to make a study of the morbidity and mortality of diabetes and to carry on public health education emphasizing early discovery, annual physical examination, adherence to diet and development of a more receptive attitude toward use of insulin.

Dinner to Dr Upham—The Columbus Academy of Medicine sponsored a dinner in honor of Dr John H. J. Upham, Columbus, President-Elect of the American Medical Association, June 5, at the Deshler-Wallick Hotel. More than 200 members of the academy and physicians from other parts of the state attended. Dr Joseph M. Dunn presided and Dr Leslie L. Bigelow was toastmaster. Speakers were Drs Herbert M. Platter, secretary of the Ohio State Medical Board, on "Dr Upham and the State Medical Board", Edwin A. Hamilton, "Dr Upham and the College of Medicine", Benjamin R. McClellan, Xenia, "Dr Upham and the American Medical Association", George V. Sheridan and Don K. Martin, former secretaries, and Charles S. Nelson, present secretary of the Ohio State Medical Association, spoke on "Dr Upham and the State Medical Association."

Society News—At a meeting of the Adams County Medical Society, West Union, June 17, speakers were Drs George W. Chabot, Peebles, on pneumonia, Robert Y. Littleton, Stoeck, fractures in country practice, and Joseph S. Rardin, Portsmouth, cesarean section.—Dr Howard L. Stitt, Cincinnati, addressed the Fayette County Medical Society, Washington Court House, June 4, on "Effect of Diet on Disease of the Nose, Throat and Respiratory Tract."—Dr John E. Greive, Cincinnati, addressed the Warren County Medical Society, Lebanon, June 2, on "The Electrocardiogram and the Coronary Circulation."—Dr Carl D. Hoy, Columbus, discussed treatment of fractures at a meeting of the Muskingum County Academy of Medicine, Zanesville, June 3.—Dr Hugo Roessler, Philadelphia, addressed the Columbus Academy of Medicine, June 1 on "Roentgenologic Considerations of Anatomy and Physiology of the Heart" and "Heart Disease, (a) Diagnostic Value of Inspecting and Palpating the Chest Wall, (b) Recent Progress in Drug Therapy."—Dr Charles F. Bowen, Columbus, addressed the Morrow County Medical Society, Mount Gilead, June 9, on treatment of cancer.—The Carroll County Medical Society was recently reorganized after having been inactive since 1911. Carroll county physicians have been affiliated with the Stark County Medical Society. Drs Charles R. Ziegler and Carl A. Lincke, Carrollton, are president and secretary, respectively.

PENNSYLVANIA

Society News—The Seventh Council District of the Medical Society of the State of Pennsylvania held a meeting at the Williamsport Country Club, July 10, with the following speakers: Drs Alexander H. Colwell, Pittsburgh "Cardiovascular Emergencies in General Practice", Walter F. Donaldson, Pittsburgh, "State Medical Society Problems", James S. Taylor, Altoona, "Obstetrical Hazards", and John O. Bower, Philadelphia, "Appendicitis". Testimonials were presented to Drs William H. Follmer, Williamsport, and James W. Ritter, Jersey Shore, both of whom have practiced more than fifty years.—The Fayette County medical and dental societies held their annual joint picnic at the Uniontown Country Club, July 8.—Dr Nathaniel W. Winkelman, Philadelphia, addressed the Lehigh County Medical Society, Allentown in June, on "Common Neurologic Conditions Met by the General Practitioner."—The Tri-County Medical Association (Dauphin, Lancaster and Lebanon counties) held a dinner meeting, June 20, at the Harrisburg Country Club, with Reed Carty, editor of the Danville Times as guest speaker. Washburn, professor of medicine, emeritus, Marquette University School of Medicine, Milwaukee, recently received a life membership in the Maternity Hospital and Dispensary Association of Milwaukee, as a tribute to "his unfailing service and devotion to humanity."

GENERAL

Exhibit at Science Meeting—The American Association for the Advancement of Science announces that applications are being received for its annual science exhibition in connection with the winter meeting at Atlantic City, December 28-January 1. Information concerning the exhibit may be obtained from Fay C. Brown, Ph.D., Smithsonian Institution, Washington, D. C.

Rocky Mountain Medical Conference—Plans for a conference in Denver in 1937 of the medical societies of the Rocky Mountain states, Colorado, New Mexico, Utah, Montana and Wyoming, have been proposed by the Colorado Medical Society. The plan, which provides that a joint meeting be held every three years with a different state acting as host, was endorsed at the recent state meetings of the Colorado and New Mexico state medical societies.

Guggenheim Foundation Increased—Former Senator and Mrs. Simon Guggenheim, New York, have recently added more than a million dollars to the endowment of the John Simon Guggenheim Foundation, founded in 1925 in memory of their son to provide means for men and women of high ability to further their work. In the eleven years of its existence the foundation has made grants to 525 persons, among whom were fifty-three working in the field of biology, including medicine.

Births and Deaths of Negroes—The U. S. Department of Commerce has compiled births and deaths of Negroes in the United States for 1934, showing 257,106 births and 182,075 deaths. Georgia had the largest number of births, 26,314, as well as of deaths, 16,475. The next largest numbers of births were in Mississippi, 25,478, North Carolina, 24,516, Alabama, 23,937, and South Carolina, 22,415. The same states in different order had the highest numbers of deaths: Alabama, 13,209,

North Carolina, 12,847, Mississippi, 12,390, and South Carolina, 11,809. Vermont reported only one Negro death, South Dakota, seven. Vermont and Idaho reported three births each, South Dakota two. Heart disease was the leading cause of death, with 27,586 fatalities. Other important causes were tuberculosis, 17,713, pneumonia, 15,999, nephritis, 14,822, cerebral hemorrhage and softening, 11,369. Cancer caused 7,849 deaths.

Society News—Dr. Carl W. Maynard, Pueblo, Colo., was chosen president-elect of the American Society of Clinical Pathologists at its annual meeting May 10, and Dr. Roy R. Kracke, Emory University, Ga., was installed as president. Dr. Frederick C. Narr, Kansas City, was made vice president, and Dr. Alfred S. Giordano, South Bend, Ind., was named secretary to serve from 1936 to 1939.—Dr. Joseph C. Beck, Chicago, was elected president of the American Bronchoscopic Society at its annual session May 27, succeeding Dr. Hermon Marshall Taylor, Jacksonville, Fla. Dr. Lyman G. Richards, Boston, was reelected secretary.—Dr. Edward H. Skinner, Kansas City, was chosen president-elect of the American Radium Society at its annual meeting in Kansas City in May. Vice presidents elected were Drs. Charles L. Martin, Dallas, Texas, and Orville N. Meland, Los Angeles, and Dr. William P. Healy, New York secretary. At the annual banquet Dr. Curtis F. Burnam, Baltimore, delivered the Janeway Lecture on "Early Experiences with Radium."—The Seaboard Medical Association of Virginia and North Carolina and of the Virginia Pharmaceutical Association took a cruise to Bermuda June 14-19 on the liner *Reliance*. The program consisted of graduate lectures by Drs. William B. Porter, Richmond, medicine, Hubert A. Royster, Raleigh, N. C., surgery, Alfred R. Shands Jr., Durham, N. C., orthopedics, Gabriel Tucker, Philadelphia, otolaryngology, Julian M. Ruffin, Durham, gastro-enterology, Claude C. Coleman, Richmond, neurology, Robert A. Ross, Durham, obstetrics and gynecology, and James B. Sidbury, Wilmington, N. C., pediatrics.—The Southern Society of Clinical Surgeons held its annual meeting in New York, June 4-5, programs being presented at Presbyterian and New York hospitals. Dr. John M. T. Finney Jr., Baltimore, was elected president, Dr. Isaac A. Bigger, Richmond, vice president, and Dr. William Perrin Nicolson Jr., Atlanta, secretary. The 1937 meeting will be held in Ann Arbor, Mich.

CANADA

Dr. Gallie Appointed Dean at Toronto—Dr. William E. Gallie, professor of surgery at the University of Toronto Faculty of Medicine, has been appointed dean of the faculty to succeed Dr. John G. Fitz Gerald. Dr. Gallie was graduated from the University of Toronto in 1903 and is a fellow of the Royal College of Surgeons of England and of Canada. In 1931 he was president of the American Orthopedic Association. Dr. Fitz Gerald resigned June 30 to take charge of a survey of methods of teaching preventive medicine sponsored by the Rockefeller Foundation.

LATIN AMERICA

Brazilian Orthopedic Society Formed—Announcement is made of the formation of the "Brazilian Society of Orthopedics and Traumatology," with headquarters in São Paulo. Dr. Luis de Rezende Puech, São Paulo, is president and Dr. Renato da Costa Bomfim, São Paulo, general secretary. The society was to hold its first congress in June at São Paulo.

FOREIGN

Bárány Jubilee Fund—Early last spring an appeal was sent out by a special committee to otolaryngologists in all countries asking them to participate in celebration of the birthday of Prof. Robert Bárány, professor of diseases of the ear, nose and throat, University of Upsala, Sweden, and winner of the Nobel Prize in medicine in 1914. They were asked to send a greeting to Professor Barany and a contribution to a Robert Bárány Jubilee Fund to be used according to his decision. Since Professor Bárány died April 8, the committee has decided to send the greetings received to his widow in Upsala and to present the contributions to the university. Interest on this fund will be used to prepare a medal to be awarded every five years by the medical faculty to the author of the best work published during the preceding five years on "The Static Sense," in the widest interpretation of the term. Collection of funds will continue till the end of 1936. Contributions will be received by Dr. Gunnar Holmgren, Sabbatsbergs Sjukhus, Stockholm, postoffice current account No. 150241.

The League of Nations and Drug Addiction

In a report just published by the League of Nations the number of drug addicts in the world is estimated at 2,000,000, of which 30,000 are in Britain. This number does not include opium smoking, a vice to which millions are addicted. The advisory committee on the opium traffic now sitting, has found that in the last five years the price of illicit morphine has increased from \$10 to \$130 an ounce. This is due to the increased restrictions, which make the drug more difficult to obtain. Traffickers have had to resort to stealing from pharmacists. In China the police are using dogs, which can scent opium when it is cleverly concealed by a smuggler or addict. Mr. Fuller, the United States representative, has suggested to the advisory committee the need for greater restrictions in harbors and in vessels in port.

The Chinese government has appealed to the league for the cooperation of the governments concerned in ending the illicit drug traffic. The investigations undertaken on behalf of the league have shown that the situation in China is partly due to the inadequate penalties imposed by Japan on Japanese drug traffickers. Accordingly the committee of the league noted with satisfaction the measures already taken by the Chinese government for suppressing the clandestine manufacture and illicit traffic. The committee also addressed an earnest appeal to Japan to apply effective penalties. It also recommended all governments to prevent their nationals from engaging in the traffic in China. In the course of the discussion the Japanese delegate referred to the statements by Colonel Sharman of Canada that Japan was the source of smuggled drugs obtained after the arrest of traffickers in Vancouver. He said that for some time the authorities at Kobe had been giving attention to the increased drug traffic with North America. The result was the arrest of twenty-six persons who constituted the center of an organization responsible for many of the cases reported from the Pacific. The Vancouver case was being studied by the Japanese government.

Recognition of Indian Medical Degrees

Some time ago the General Medical Council withdrew recognition of Indian medical degrees because it was not satisfied with the standard of the examinations. In his presidential address to the council, Sir Norman Walker made an important statement on the subject. He said that the council had the duty of ascertaining the sufficiency of the examinations leading to qualification. Before 1920 it accepted for registration the degrees and diploma of the Universities of Bombay, Calcutta, Lucknow, Madras and the Punjab. In 1921 a questionnaire was addressed to these universities and the replies showed that the teaching of midwifery did not except in Madras, reach a standard that would be recognized in the United Kingdom. To solve a difficult question he had accepted an invitation from the secretary of state for India to proceed to that country and discuss the difficulties with the authorities there. In his report made in 1922 he expressed the opinion that each of the universities could bring its regulations sufficiently into accordance with the requirements of the council to enable it to recognize its diploma. He proposed that Col. R. A. Needham, deputy director general of the Indian Medical Service (the medical service of the army in India) should be made medical inspector of the medical teaching in the Indian schools. Acting on his report the council recognized the degrees. On revisiting India in 1926 he found that general improvement had been made

almost everywhere, and not least in obstetrics. In 1933 an act was passed constituting a medical council of India on lines similar to those of the General Medical Council in England. Bombay had in the Ness Wadia Maternity Hospital the best maternity hospital he had seen anywhere, with an even larger number of cases than the Rotunda of Dublin. The Indian Medical Council, which now inspected and visited the Indian universities, had forwarded reports on these. The executive committee of the General Medical Council had resolved that the degrees of M.B., B.S., granted by the Universities of Bombay, Lucknow and Madras, which formerly were registrable, should again be recognized for registration if granted after May 1935.

THE NUMBER OF MEDICAL STUDENTS

The president announced that the number of medical students registered in England in 1935 was 1,363, the second highest on record, twelve less than in the peak year of 1919, and 269 more than last year. Scotland had five fewer at 719 and Ireland eleven fewer at 521.

The Value of Snuff Taking

The practice of snuff taking has declined greatly in England. It was at its height in the eighteenth century and continued down to the middle of the nineteenth, when it fell away. Letters in the *Times* from Sir Buckstone Browne (a retired urologist and a munificent donor to the Royal College of Surgeons) advocating snuff taking as a prophylactic against colds in the head has revived interest in the subject and led to a paper on it, which was read by Dr. J. D. Rolleston before the Society for the Study of Inebriety. He said that the habit, which once was in vogue in court circles, seemed likely at one time to find its last refuge in infirmaries and mental hospitals. He suggested that one reason for its disfavor was the great objection of Queen Victoria to any one sneezing in her presence. Sir Buckstone Browne told the society that his experience with the virtues of snuff dated from his early days in practice when, after operations early in the morning and seeing patients more or less continuously until the afternoon, when he had to start on his carriage visits, very tired, he found snuff refreshing and useful. He attributed his immunity from colds in the head to the action of snuff in stimulating the nasal mucous membrane and producing a flow of mucus. Pepper and other irritants would of course also induce sneezing, but tobacco snuff was more than an irritant. It was agreeable to most people, stimulating at first and then narcotic and astringent to the mucous membrane. His advice to the audience was: "If you think you are sickening for a cold in the head, take a good pinch of snuff before going to bed and you will awake quite well in the morning."

Some Reduction of Road Accidents

The constant adoption of new precautions against road accidents seems to have made some impression, as the figures for 1935 show some reduction in their number. In that year the road accidents numbered 195,892, against 204,710 in 1933. The number of persons killed or injured was 228,228, against 238,946 in the previous year. The number of killed was 6,502, against 7,343. Accidents in London amounted to 50,207, of which 1,077 were fatal. The number of persons killed or injured numbered 56,072.

Precautions Against Air Raids

The extensive nature of the precautions now being taken against air raids is shown by a scheme brought forward by the borough council of Croydon (a populous district on the outskirts of London). It involves the training of 300 volunteer firemen, the appointment of thirty auxiliary turncocks, the purchase of extra fire appliances, extension of the fire alarm system to all hospitals and to future first aid stations, and the acquisition of gas masks and protective clothing. It is also

proposed to mobilize local physicians for duty at first aid and casualty clearing stations. The Red Cross Society and the John Ambulance Brigade will continue their present training of a corps of 500 men and 500 women for specific duties during air attacks. The scheme also includes equipment for the decontamination of people, vehicles and roadways, and for the registration of private vehicles for ambulance and fire brigade service. A register is to be opened of persons willing to act as street wardens to see that every householder is acquainted with the official instructions regarding precautions, and arrangements have been made for rendering one room gas proof.

Relation of Typhoid to Shell-Fish

The relation of typhoid to shell-fish on the southern coast of France was the subject of a paper by one well qualified to discuss it, Teissoniere, at the April 23 meeting of the Academie de médecine of Paris. A law which has been in force since 1923 governing the cultivation of oysters ought to be extended to all shell-fish, especially clams. Since the oyster beds have been subjected to government control, not a single case of typhoid in Nice or Cannes has been found that was due to the ingestion of oysters. On the other hand, thirty-nine cases of typhoid at Nice and twenty at Cannes were traced to the ingestion of clams and similar shell-fish. The bacteriologic test, consisting in determining the number of *B. coli* organisms to 100 cc., cannot be strictly applied to shell-fish. For example, if oysters contain from 100 to 700 *B. coli* organisms per liter of water they are usually regarded as not being safe to eat, yet a large quantity of such oysters were consumed at Cannes without a single case of typhoid developing. In the Netherlands and the United States, according to Teissoniere, a *B. coli* content of 10,000 organisms per quart (liter) is considered safe for oysters, while in England the figure is from 5,000 to 10,000 per quart. These percentages are much higher than hygienists consider safe for drinking water, wherefore no figure has been established in France as yet for all shell-fish. It is far more important from the standpoint of the public health officer to study the topography of the region in which the beds are located and the method of transportation.

In spite of the assertion that it is impossible to obtain edible clams, Teissoniere maintains that this can be done. Such establishments exist along the Mediterranean coast of France. Twenty-six bacteriologic analyses taken Oct. 26, 1935, in one of the beds where clams are cultivated reveal the absence of *B. coli*, whereas specimens taken near Bouzigues, one of the seaports, show 1,000 *B. coli* organisms per liter. The danger of infection arises chiefly in clams, which are obtained by fishermen, because contamination in such cases is difficult to control except in the case of oysters. Clam beds exist all along the shore, so that the limitation to certain areas is not as easily carried out for clams as for oysters, which are limited to certain areas. Clams prefer to grow in water that is not salty and hence prefer water coming from rivers. These are usually near cities, the sewers of which empty into the rivers and thus favor absorption of infected water by the clams. Therefore fishing for clams ought to be prohibited here. In cities such as Cannes and Nice, cases of typhoid from polluted oysters no longer occur, but in other Mediterranean cities such as Toulon and Marseilles, this is not the case. 265 cases of typhoid were reported at Marseilles last year and 118 at Toulon. Of the latter, forty-three were due to the ingestion of infected shell-fish. The crux of the situation is to have better control over the shell-fish, especially clams.

Cardiac Erethism in Adolescents

At the Societe medicale des hopitaux of Paris, April 24, an army surgeon, Bénard, reported his observations of recruits during the past seventeen years. Some young men were unable to march at a rapid pace or do gymnastic exercises without complaining of so much palpitation and dyspnea that they were obliged to cease walking or working in the gymnasium. The question was whether these recruits were malingerers or whether some form of cardiac insufficiency existed. For a long time Bénard was unable to find any cause for this erethism or increased cardiac activity. He was only able to note on the recruits card that he seemed to be truthful in his complaints, that no valvular lesion could be found and that he should be excused from gymnastic exercises. The late Professor Vaquez was the first cardiologist to employ the term "erethism" to characterize "a certain degree of increased cardiac activity, felt as palpitation and heard on auscultation, at times difficult to distinguish from the presystolic purring of a mitral stenosis." Bénard described an average case. "Erethism" is most commonly observed between the ages of 10 and 18 years but can continue to between 22 and 25 years. The most common subjective complaint is dyspnea on exertion, often after having run a distance of 50 yards. The dyspnea and rapid heart action decrease as soon as the physical effort ceases. In others, the chief complaint is of palpitation on exertion. In about half the cases, auscultation reveals a systolic murmur at the base at the level of the second left intercostal space, best heard as a rule when the recruit is lying down, rarely better on standing up. Clinically, one can distinguish an atypical type (form fruste), a typical type, with palpitation and dyspnea and a rare type with decompensation. As objective evidence, Bénard presented the energy of the heart's contraction, murmur over the pulmonary area, increased size of middle portion of aortic arch, absence of enlargement of left auricle in a posterior direction, and certain electrocardiographic changes. He believes that these cases of "erethism" are due to a congenital stenosis of the pulmonary artery. The prognosis is good and no special treatment is indicated. Such cases have often been diagnosed as "war heart" or "irritable heart" and at times as mitral stenosis.

Acute Leukemia After Treatment of Arthritis with Gold Salts

Another one of the potential complications of the use of gold salts in the treatment of such diseases as pulmonary tuberculosis and arthritis was reported by Boulon, Coste, Uhry and Antonelli at the April 24 meeting of the Societe medicale des hopitaux of Paris. A woman, aged 51, was admitted to the hospital Oct. 11, 1934, with the diagnosis of chronic arthritis deformans and an associated psoriasis, for which she had been treated in the outpatient department since 1930. Following a first series of gold salts in 1931 there was a marked improvement of the arthritis. The treatment was resumed in February 1934 but discontinued in May. Several injections of gold salts (chrysalbin) in small amounts were given about Oct. 15, 1934. The blood examination about two and again four weeks later revealed a marked decrease of red and white cells as well as of the polymorphonuclear leukocytes. Two months later the patient had a severe sore throat and a furunculosis of the gluteal and elbow regions complicated by extensive subcutaneous ecchymoses, necrosis and bleeding from the gums. The blood picture at this time was that of an agranulocytosis and later that of an acute leukemia. The patient died Jan. 14, 1935, and the necropsy revealed a glomerulonephritis without involvement of the tubules, and marked cellular infiltration of the liver and of the hematopoietic viscera. The treatment with gold salts was considered to be responsible for the acute leukemia. A similar case was reported by Coste in 1934.

According to the authors of this paper, gold salts should be placed in the same group as roentgen rays, radioactive agents, benzene and tar as giving rise to an acute leukemia

Public Health at the 1937 Paris Exposition

A certain number of daily conferences on public health questions are being arranged for the 1937 Paris Exposition of Arts and Technic in Modern Life. The five subjects chosen for general discussion include clothing, food, transports and physical education (games and sports). An attempt will be made to show that violation of the laws of hygiene favors development of disease, and the various resultant forms of the latter will be the subject of a number of conferences. A public health code will be formulated to which every one engaged in the study of the preservation of the race can refer. Daily conferences are to be arranged on the subjects of maternity and infancy, school hygiene, military medicine and pharmacy, hygiene in the colonies, aviation and merchant marine, urbanism, dwellings and social organization. The journal *Social Hygiene* has assumed the task of organizing these international conferences on public health, to be held July 1-10, 1937. Special tourist rates, lodgings and all other information can be obtained through the secretary, 2 rue Chauchat, Paris. The conference committee is especially anxious to obtain the cooperation of physicians, dentists, druggists, veterinary surgeons, architects, city planners, sanitary engineers, social workers, nurses and industrial organizations.

Rechloridation Treatment of Acute Nephritis

The treatment of all degrees of uremia by the administration of sodium chloride in concentrated solutions has been the subject of a number of papers read during the last two years at meetings of the principal Paris societies. An instance of the value of this treatment was presented by Lemierre and his associates at the March 20 meeting of the Société médicale des hôpitaux. The patient began to vomit about eight days before admission in January 1935. The emesis continued without a free interval for the entire eight days, so that ingestion of solid or liquid food was impossible. No cause could be found for the vomiting. There was a history of an attack of diphtheria in 1924.

On account of the presence of a grayish white exudate on the tonsils, the inner aspect of the cheeks and the soft palate, the patient had been sent to the hospital as having diphtheria, but this diagnosis was discarded because no specific bacilli were found. The vomiting had stopped shortly before admission to the hospital, but the marked stomatitis and fetid strongly ammoniacal odor of the breath led to the suspicion of uremia as the underlying cause. Examination of the blood revealed a urea content of 415 mg per hundred cubic centimeters and a marked hypochloremia but an almost normal carbon dioxide combining power (47.9 volumes per cent). On the third day after admission a generalized scarlatiniform eruption appeared. The urine examination revealed no abnormal elements. January 31 (fourth day), 500 cc of 0.9 per cent solution of sodium chloride was given subcutaneously. This was repeated during the next three days. In addition, 75 cc of a 20 per cent solution of sodium chloride was given intravenously. February 2, 30 cc. of the same hypertonic solution the following day, and 100 cc. of a 10 per cent solution of sodium chloride during the next two days. After February 7, the eruption had disappeared and the general condition improved rapidly. February 22 the blood urea was normal 29 mg per hundred cubic centimeters. Lemierre and associates believed that the pharyngostomatitis and ammoniacal odor of the breath were of uremic origin. Under the influence of the rechloridation treatment the high blood urea content disappeared and the hypochloremia rose to normal. The renal insufficiency and uremia were the direct results of the hypochloremia. Two days after the beginning of

the rechloridation treatment the plasma chlorine rose to 241 mEq and at the same time the evidences of urea retention in the blood receded. The cause of the severe emesis remains obscure. If the high blood urea had been due to a nephritis alone, there would have been a marked fall in the alkali reserve, which in this case was almost normal.

Polyneuritis Produced by Addition of Lactic Acid to Diet

As a result of his experiments, Lecocq has reached the following conclusions:

- 1 The addition of 10 per cent lactic acid in a diet suffices to prevent utilization by pigeons of large doses of vitamin B. The pigeons die presenting symptoms of attacks of polyneuritis as in avitaminosis B.
- 2 Such a polyneuritis occurs whether glucides are given or not, even though the predominant element of the diet is constituted by proteins or lipoids.
- 3 The impregnation of the tissues by the lactic acid, which is the direct effect of the ingestion of such diets, appears to bear an etiologic relation to the polyneuritis attacks.

BERLIN

(From Our Regular Correspondent)

May 11, 1936.

The Problem of Bacterial Mutation

Prof. W. Seiffert, in elucidating some aspects of the question of bacterial mutation, before the Berlin Microbiological Society, said that in dealing with the variability of bacteria distinction must be made between (1) true mutation or qualitative alteration of the genes, (2) changes in the arrangement of the genes (for example, deficiency or excess of a gene through bacterial fusion) and (3) modifications, that is, plasmatically conditioned variations without change in the gene. The existence of true bacterial mutation can be demonstrated in experimentation by means of the rate of mutation. The manifestations of bacterial variants does not bear relationship to the environment but is in proportion to the number of bacteria. The more bacteria developed the greater the number of variants, especially if the cultures are kept in cellophane tubes according to the Gildemeister method (which permits the passing out of the products of metabolism and the passing in of nutrient substances). The type of nutrient medium employed (nutrient bouillon, Ramon's toxin bouillon, synthetic ammonium lactate) is immaterial. Faulty nutrition inhibits growth, hence the appearance of variants. Changes in the arrangement of genes may take place. A paratyphoid B strain, for example, may appear in a nongaseous form. It is possible to breed from this original form whole R and S forms among which a gaseous retromutation never appears. The gene of gas formation thus would seem to be lost. In addition, observations of a Gartner strain that in frequently repeated experiments produced only R forms evidenced that R and S forms propagate in apparently equal numbers.

In studying those modifications which are conditioned by environment, particular interest attaches to the "permanent modification" theory of Jollos, according to which modifications are phenomena of accommodation transferred from one generation to another.

On the basis of his own investigations, Seiffert states that the permanent modifications do not exist. His reasons are: 1. The permanent modifications of bacteria are always connected with natural modifications of bacteria in the vine-leaf shape of colon bacilli on gelatin and are not susceptible to habituation (for example, the normal growth of colon bacilli in the retrotransmission from gelatin to agar). Not the modification itself, then, but the capability of manifesting modification is hereditary. Mutations without specific external cause which bear outward resemblance to a modification are, however, possible. 2. The natural func-

ions of bacteria are not increased by exercise (for example, the formation of hemolysin in staphylococci is not increased by blood agar passage) 3 A stimulation of natural functions of toxin formation of staphylococci by carbon dioxide, for example) is not transferable from generation to generation (demonstrated by experimentation with staphylococci) 4 The reversion in so-called permanent modifications is not a gradual process common to all individuals but rather represents a complete change in certain single persons Reports in the literature of "permanent modifications" frequently mention the processes of selection, which are complicated by the appearance of true mutants

The results of Seiffert's rejection of permanent modifications are of practical importance 1 Since each type possesses its own sharply outlined rate of mutation which keeps it within the bounds of the type character, mutations from type to type are categorically rejected Single characters may vary completely and independently, for example, characters of colon bacilli such as indole formation, gas formation, clotting of milk and decomposition of lactose If typhoid bacilli can be developed from colon bacilli through mutation, then either intermediate stages must exist (namely, typhoid bacilli capable of forming gas or indole or of decomposing lactose), or else superimposed unspecific forms must appear in experimentation, presumably produced by fission of colon bacilli as well as typhoid bacilli However, neither of these conditions eventuates On the other hand, type to type mutations are possible in the Salmonella group, for example, wherein unspecific variants of the R form are actually found, one type overlapping the other The concept of a specialization of differing types from one and the same R form is therefore permissible with regard to this group 2 The hypothesis that by habituation to the animal organism saprophytes may be changed to parasites or avirulent strains to virulent strains is untenable The only value of the animal experiment is that it permits, from a mixture of virulent and avirulent micro-organisms, the virulent ones to be selected and their growth increased 3 There is no hereditary degeneration nor any nutrient medium degeneration Degeneration takes place only in the phenotype, it may be conditioned by the age of the cultures (old gram-negative staphylococci, for example) but may also appear in fresh cultures subjected to unfavorable influences (involution) Since mutability of bacteria is not a degenerative phenomenon, the appearance may be expected of mutants, without being exposed to selection, in any environment which favors growth to the same degree as the nutrient bouillon 4 There are no developmental cycles of bacteria, nor are there any fertilizing processes (if, for example, a gaseous paratyphoid R form and a nongaseous paratyphoid S form are brought together in bouillon, only the original forms will appear in cultures and the gaseous S form will be as regularly absent as the nongaseous R form, both the later types will appear, however, if a fertilization, that is, an interchange of genes, takes place) The Pettenkofer theory is likewise rejected, since the spherical formation appears only in certain variants, when these variants have been obtained from a form entirely free of Pettenkofer's parasites of bacteria It is indicated from thoroughgoing experimentation that bacterial deformations result from a (variable) salt sensitivity alkalis favor cytolysis (according to tests with sodium chloride and lithium chloride) and magnesium inhibits the cell division (filiform growth)

The Physicians' Mutual Insurance Association

The Deutsche Aertzeversicherung auf Gegenseitigkeit has been in existence more than fifty years According to the annual report there were on Dec. 31, 1934, some 20 000 German physicians representing total insurance holdings valued at 327 900 000 reichsmarks The annuity rates of policyholders are based on an amount ten times the yearly premium In

1934, 7,700,000 reichsmarks was collected in premiums due, earned increment on the capital amounted to 3 000,000 reichsmarks, income from other sources to 6,200,000 reichsmarks For disabilities incurred, 4,200,000 reichsmarks was paid out in 1933 and 52,500,000 in 1934 Despite the further decrease, interest on mortgages as authorized by the national government as of Jan 1, 1934, still showed an average yield of 6 per cent on the total capital investment According to the statement of financial condition on Dec 31, 1934, the assets were invested, among other things, 7.3 per cent in real estate, 71.3 per cent in mortgages, 15.6 per cent in securities and loans on securities Costs of administration totaled around 240,000 reichsmarks, that is, 3.1 per cent of the current income from annual premiums This represents a figure about half that of the insurance organization, the administrative expenses of which rank next lowest to that of the Physicians' Insurance It also represents an amount equal to one fourth, at most, of the administrative costs of the great commercial insurance companies

The mortality among the insured was below expectancy and the favorable progress of the disabled was noteworthy

Gas Casualties During the World War

J Wirth, who served during the war as technical adviser on antigas defense and compiler of gas casualties for the Prussian war ministry, recently addressed the Medical Society of Frankfurt-on-Main He gave the following figures for the proportion of gassed patients to the total number of the German wounded

| Period | Percentage of Asphyxia Cases | Number of Asphyxia Cases in Hospital |
|-----------|------------------------------|--------------------------------------|
| 1914-1915 | 0.01 | 87 |
| 1916-1918 | 0.85 | 6 485 |
| 1916-1917 | 2.2 | 17 489 |
| 1917-1918 | 4.6 | 43 609 |

For the French army the corresponding percentage was 17.5 in 1917-1918, and that for the American forces, still following Wirth's statistics, was 31.5 per cent The number of men on the German side gassed during 1918 amounted to 15.6 per thousand Among the British the rate was 57.2 Wirth attributes this noteworthy disparity to the more effective conduct of gas warfare by the Germans as well as to their better defensive measures and drills against gas attack

The mortality among those suffering from war gas asphyxia depends on several factors 1 The nature of the attack, that is, the frequency with which different methods of projection (grenades, projectors, gas mines) were used The latter two methods of gas attack are the more deadly because they permit a greater concentration of gas at the objective of attack 2 The measures taken for protection against gas and the efficacy of discipline in face of surprise attacks in particular 3 On the precise circumstances of the asphyxia and whether or not dichloroethylsulfide (yellow cross or mustard gas) was the principal substance employed Although mustard gas is responsible for the largest number of casualties, especially because of the blistering of the skin that accompanies the asphyxiation, it causes fewer fatalities than certain other gases, "green cross," for example An average of from 6 to 7 per cent of the asphyxia cases terminated fatally Of importance too are the casualties inflicted by carbon monoxide (in concentration of more than 0.05 per cent) which is released in enemy dugouts by the explosion of gas mines, dangerous concentrations are found in shell craters as well

With regard to the importance of casualties due to gas warfare, Senior Staff Surgeon Muntzsch, who has made a special study of the question for the military authorities, calculates that, among all the forces engaged on the Western Front in 1918, gas asphyxia cases accounted for 18 per cent of the total

number of wounded Muntsch's further investigations elicited the noteworthy fact that among the French during the operations in Champagne from Aug 6 to Sept 25, 1918, 42,702 men suffering from gas asphyxia were given treatment on the hospital trains, a number equal to 30 per cent of the total number of wounded received by these trains during the same action

Data are lacking which would help determine the damage caused by gases released in aerial bombardment during the World War, but in any case the bombing of a town depends for its value on the shattering and incendiary effect. The assumption may be made, however, that the effectiveness of the aerial gas attack (like that of the ground attack with projectors or mines) depends largely on two factors: the ability of the raider to surprise the enemy and the amount of concentration at the point of striking. Hence the drilling and protection against gas attacks among the civil population at home should be kept on a level with that practiced by the army in the field.

ITALY

(From Our Regular Correspondent)

May 4, 1936

Society Reunion

The Accademia Medica of Rome met recently under the chairmanship of Professor Alessandri. Professor Penso spoke on a disease of hog herders. The incubation period lasts several weeks and is followed by intestinal disturbances, after which a meningeal syndrome develops. Laboratory investigations have given negative results as yet. Recovery usually occurs.

Professor Baglioni discussed the effects of the administration of gelatin and casein and the results produced by the addition of mineral salts to the administration of proteins. The fact, also noted by Zagami, that fasting stimulates the accumulation of nitrogen substances during readjustment, although it explains the nitrogen metabolism during convalescence from acute diseases, proves that a parallelism between the increase of weight and the retention of nitrogen by the organism does not exist. This fact was verified by the results of Baglioni's experiments on the nitrogen metabolism of rats fed with special proteins.

Professor Testoni reviewed his experiments, which proved that splenectomized animals regain weight by readjustment following fasting more quickly than normal animals.

Professor Testoni studied the passage of certain drugs through the placenta. The passage of thallium from mother to fetus depends on the dose, duration of treatment, period of evolution of pregnancy and species of animal. Cataract and iritis are the only lesions detectable in fetuses from animals chronically intoxicated by thallium acetate. Probably these pathologic conditions found in the fetuses are due to a selective action of thallium on the parathyroids.

Dr. Liberti discussed the cerebrospinal fluid in human tetanus. The tetanus toxin cannot be detected in the fluid, even by resorting to special procedures, such as chloroformization, etherization and production of experimental meningitis. Antitoxin is detectable in the fluid in all cases but especially after provocation by chemical irritation of the meninges.

Drs. Seranni and Lolli discussed the effects of insulin and morphine on glycemia in normal persons and in patients suffering from diabetes mellitus. Morphine given alone causes hyperglycemia which is more marked in diabetic than in normal persons. Morphine when given in association with insulin increases the hypoglycemic action of the latter both in normal persons and in the diabetic.

Dr. Minz studied the action of insulin on provoked alcoholism in seven diabetic patients. Alcoholism in persons with diabetes is not lowered by insulin, although it is lowered by the latter in normal persons.

Diphtheria in the Netherlands

A report by Dr. Josephus Jitta containing data on the morbidity from diphtheria in the Netherlands has been submitted to the International Bureau of Hygiene.

The following table represents the incidence of diphtheria cases among the total population of some 8,000,000 inhabitants of the kingdom during the five years from 1930 to 1934.

Incidence of Diphtheria in the Netherlands

| | 1930 | 1931 | 1932 | 1933 | 1934 |
|----------------------------------|-------|-------|-------|-------|-------|
| Cases reported | 7 450 | 5 693 | 5,353 | 4,251 | 2,999 |
| Deaths | 439 | 311 | 272 | 193 | 143 |
| Morbidity per 10 000 population | 9.51 | 7.19 | 6.64 | 5.19 | 3.61 |
| Death rate per 10 000 population | 0.56 | 0.39 | 0.34 | 0.24 | 0.17 |
| Percentage of fatal cases | 5.9 | 5.5 | 5.1 | 4.5 | 4.8 |

No official instructions are issued prescribing or recommending antidiphtheritic immunization. The official public health organs, however, carry on propaganda with the tacit approval of the government. In North Holland Province, among a total population of 325,000 residing in fifty communes, not including Amsterdam and Haarlem, 29,200 were inoculated. It may be accepted as a fact that by Jan 1, 1935, 25 per cent of the children of North Holland had been inoculated under the supervision of the official examiner. In Amsterdam from 1929 to Jan 1, 1935, 37,969 children were presented for immunization and 32,162 underwent the complete treatment.

Antivenereal Disease Campaign

In the conduct of an antivenereal disease campaign, each country selects a method in keeping with the national character. This explains why in the Netherlands the organization of this campaign is imbued with a spirit of independence and of hatred for coercive measures. In place of official examinations of the genitalia of prostitutes and the compulsory registration of those infected, a policy based on persuasion and free will has been instituted. This operates through therapeutic stations open during the evening hours. The work of the stations is supplemented by consultation offices and by the cooperating services of women social workers who visit the infected women undergoing treatment. Thus diseased prostitutes, assured that no compulsion is involved, submit voluntarily to treatment. It is the same approach that has been used with notable success in the fight on tuberculosis. In addition, propaganda against the venereal diseases is carried on through lectures, moving pictures, and so on. The results in big cities such as Rotterdam have been most encouraging.

The Number of Physicians

The report of the Limburg Commission on the future of academic graduates has been published. It shows that during the period from 1905 to 1934 the number of general practitioners increased from 2,322 to 3,548, while the number of specialists increased from 347 to 1,241. The total number of physicians in the Netherlands including army and employed civilian physicians, amounts to 5,886. In the Dutch East Indies there are still 1,200 physicians, 700 of whom hold diplomas from the home country. Of more recent graduates 60 per cent have not attained the level of an annual income of 5,000 florins in five years subsequent to receiving their degrees. About 70 per cent of medical students complete their studies. 534 young physicians are seeking employment. In 1934 there was one physician to each 1,720 of population. In 1939 the ratio will be one to each 1,360 of population.

Marriages

WOLFGANG FRITZ JUSTUS VOGEL of Huntingdon, Pa, to DR HELGA ELIZABETH STREITBERG of Leipzig, Germany, April 9

LUTHER F GRANT, Liberty, N Y, to DR SIRKA ELISABETH VUORNOS, Boston, in New York, April 27

JAMES HENDERSON CHERRY, Asheville, N C, to Miss Katherine G Buck of Bald Mountain, April 18

LEO BOYES FREEMAN, Germantown, Pa, to DR RUTH FRAZER HARRAL of Drexel Hill, June 20

BLAKE M LANCASTER, Manatee, Fla, to Mrs Edward Livingston of Bradenton, April 25

ELDON L BOLTON, Biloxi, Miss, to Miss Carolyn McKellar of Memphis, Tenn, May 23

WILLIAM THOMAS BRAUN JR to Miss Marion Helen Brigha, both of Baltimore, May 17

LESTER J GREENBERG to Miss Janet Bogomolny, both of Brooklyn, May 31

THOMAS A ANGLAND to Miss Betty Brush, both of Yakima, Wash, April 25

Deaths

Wells Ferrin Smith, Little Rock, Ark, Beaumont Hospital Medical College, St Louis, 1898, member of the Arkansas Medical Society, president of the Arkansas State Board of Health, past president of the State Medical Board of the Arkansas Medical Society, professor of surgery, University of Arkansas School of Medicine, member of the board of governors and fellow of the American College of Surgeons, member of the surgical staff of the Baptist State Hospital, member of the staff of St Vincent's Infirmary and the Children's Home Hospital, consulting surgeon to the Little Rock General and Veterans' Administration hospitals, and the Working Women's Home, aged 64, district surgeon to the Missouri Pacific Hospital, where he died, May 19, of cerebral hemorrhage

Campbell Palmer Howard, Montreal, Que, McGill University Faculty of Medicine, Montreal, 1901, professor of medicine at his alma mater, at one time head of the department of internal medicine, State University of Iowa College of Medicine Iowa City, member and past president of the Association of American Physicians, member of the American Society of Clinical Investigation and the American Association of Pathologists and Bacteriologists, served with the Canadian Army in the World War director of the department of medicine, Montreal General Hospital, member of the senate of McGill University, contributor to several systems of medicine and to the periodical literature, aged 59, died suddenly, June 3, while in Santa Monica, Calif, of pulmonary embolism following phlebitis

George Andrew Hare of Fresno, Calif, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1887, member of the House of Delegates of the American Medical Association, 1912-1915, past president of the American Academy of Medicine and of the Fresno County Medical Society, formerly vice president of the California Medical Association, in 1906 delegate to the International Medical Congress in Lisbon, at one time superintendent of the Washington Sanitarium, Washington, D C formerly associate editor of 'Life and Health', aged 78, died, April 4, of carcinoma of the prostate gland

Wesley Wilbur Beckett of Los Angeles, University of Southern California College of Medicine, Los Angeles, 1888 a practitioner in Los Angeles since 1889, professor of gynecology and surgery and later emeritus professor of surgery at his alma mater, past president of the California Medical Association, Los Angeles County Medical Society, Los Angeles Clinical and Pathological Society and the Southern California Medical Society, formerly member of the city board of health, medical director of the Pacific Mutual Life Insurance Company, aged 79 died, June 3, of cerebral hemorrhage

Melbourne Clements, Seattle, Rush Medical College, Chicago, 1910 at one time a practitioner in Chicago, formerly assistant demonstrator of dermatology, Jefferson Medical College of Philadelphia assistant in surgery (genito urinary) and clinical associate in surgery (genito urinary) at his alma mater, during the World War served as chief medical officer of the

transport *Wilhelmina*, graduated from the Cincinnati Conservatory of Music and was a violinist in the medical society orchestra, aged 51, died, April 26, in the Firland Sanatorium of pulmonary tuberculosis

James Walter Walker, Fayetteville, Ark, Washington University School of Medicine, St Louis, 1915, member of the Arkansas Medical Society, past president and secretary of the Washington County Medical Society, was on the reserve list of the Reserve Officers Training Corps during the World War, fellow of the American College of Surgeons, formerly secretary of the State Medical Board of the Arkansas Medical Society, county health officer, member of the staff of the Fayetteville City Hospital, aged 56, died, May 4

Joseph Norman Fogarty, Daytona Beach, Fla, Columbia University College of Physicians and Surgeons, New York, 1898, member of the Florida Medical Association, formerly secretary of the Monroe County Medical Society, at one time member of the state board of medical examiners, health officer of Key West, mayor of Key West and St Augustine and member of the state legislature, for many years chief surgeon of the Florida East Coast Railroad, aged 60, died, May 5, in the New York Post-Graduate Hospital

Charles Sherman Little, Thiells, N Y, Dartmouth Medical School, Hanover, N H, 1896, past president of the Rockland County Medical Society, member of the Medical Society of the State of New York and the New England Society of Psychiatry, past president of the American Association on Mental Deficiency, since 1910 superintendent of the Letchworth Village, superintendent of the State School for the Feeble-minded, Laconia, N H, from 1902 to 1910, aged 67, died, June 6, of angina pectoris

Archibald Campbell MacLeish of Los Angeles, University of Southern California College of Medicine, Los Angeles, 1908, associate clinical professor of surgery (ophthalmology) at his alma mater, member of the Pacific Coast Oto-Ophthalmological Society, fellow of the American College of Surgeons member of the staff of the Hospital of the Good Samaritan and the Barlow Sanitarium, aged 52, died suddenly, May 3

Hugh MacDougal Hart, Newark, N J, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1894, member of the Medical Society of New Jersey, for many years surgeon for the city fire department, aged 63, died, April 24, of congenital polycystic kidneys and cardiovascular renal disease

Joseph Budd Hulett, Middletown, N Y, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1887, member of the Medical Society of the State of New York, for many years member of the board of health, died, April 8, of cerebral hemorrhage and bronchopneumonia

Albert Triplett Horn, Chicago, College of Physicians and Surgeons, Baltimore, 1904, member of the Illinois State Medical Society, formerly assistant in anatomy, Northwestern University Medical School, on the staff of the Auburn Park Hospital, aged 56, died suddenly, April 19, of coronary thrombosis

Alexander Francis Mosher of South Glens Falls, N Y, Albany (N Y) Medical College, 1909, had been health officer of the consolidated health district comprising the town of Moreau and the village of South Glens Falls since 1926, aged 48, died, April 25, of endocarditis and myocarditis

George Washington Gale, Saugus, Mass Berkshire Medical College, Pittsfield, 1861, member of the Massachusetts Medical Society, Civil War veteran, formerly chairman of the board of health and school committee, aged 99, died, April 20, of arteriosclerosis and cerebral hemorrhage

Rodney Hall Richardson, Reno, Nev, University of Pennsylvania Department of Medicine, Philadelphia, 1884, member of the Nevada State Medical Association, at one time superintendent of the Nevada State Hospital for Mental Diseases, aged 75, died, May 1

James Otho Hardy, Las Animas, Colo Marion-Sims College of Medicine, St Louis, 1897, member of the Colorado State Medical Society, for many years county physician and county health officer, served during the World War, aged 68, died, April 18, of angina pectoris

David William Gass, Pickensville, Ala. Birmingham Medical College 1899, member of the Medical Association of the State of Alabama, veteran of the Spanish-American War, aged 68 died, April 19, in the Veterans' Administration Facility, Danville, Ill, of meningitis

Samuel E Hibbs, Uniontown Pa Western Pennsylvania Medical College, Pittsburgh, 1904 member of the Medical Society of the State of Pennsylvania aged 61, on the staff of the Uniontown Hospital, where he died, April 1, of carcinoma of the prostate.

Paul Allen Fox ♂ Beloit, Wis., Rush Medical College, Chicago, 1895 past president of the Rock County Medical Society, president of the Beloit Clinic, on the staff of the Beloit Municipal Hospital, aged 64, died, April 27, of coronary occlusion.

John J Osburn, Wheeling, W Va., Starling Medical College Columbus, 1882, member of the West Virginia State Medical Association, on the staff of the Wheeling Hospital, aged 77, died, April 17, at Tuscaloosa, Ala., of facial erysipelas.

James W Nixon, Holloway, Mich., Western University Faculty of Medicine London, Ont., Canada, 1892 member of the Michigan State Medical Society, aged 67, died, April 12, in the Emma L Birby Hospital, Adrian, of Vincent's angina.

William Wood Hobbs ♂ Raytown, Mo., University Medical College of Kansas City, 1904, on the staff of the Menorah Hospital, Kansas City, aged 54, died, April 14, in a hotel at Kansas City, of a self-inflicted bullet wound.

William Columbus Hendrick, Shreveport La. Memphis (Tenn.) Hospital Medical College 1908, member of the State Medical Association of Texas, aged 62, died, April 12, in the Tri-State Hospital, of chronic myocarditis.

Horace Stoffet Saylor, Altoona, Pa., Temple University School of Medicine, Philadelphia, 1915, for many years chief doctor for the Pennsylvania Railroad Company, aged 47, died, April 5, of posttraumatic epilepsy.

Alfred Clarence Wilhelm ♂ Traverse City Mich. Chicago College of Medicine and Surgery, 1913, served during the World War, on the staff of the James Decker Munson Hospital, aged 46, died, April 9.

Burton D Giddings, Niles Mich. Hahnemann Medical College and Hospital, Chicago 1903 member of the Michigan State Medical Society, aged 62, died, April 29, of myocarditis and coronary sclerosis.

Ever A Olson, Osseo Wis. College of Physicians and Surgeons, Keokuk, Iowa, 1880, aged 85 died April 21 in the Sacred Heart Hospital, Eau Claire, of thrombosis of the superior mesenteric artery.

Ernest Leslie Bickford, Seattle, Missouri Medical College, St. Louis, 1890, served during the World War aged 69 died April 27, in the Veterans' Administration Facility, Salt Lake City, of heart disease.

Daniel Guedalyah Golding ♂ Santa Monica Calif. Jefferson Medical College of Philadelphia, 1890, aged 65 on the staff of the Santa Monica Hospital, where he died, April 27 of cerebral hemorrhage.

Edgar Joseph Geisinger, Unionville Mo., College of Physicians and Surgeons, Keokuk Ia., 1878, for many years postmaster, aged 86, died, April 23, of chronic nephritis and prostate obstruction.

George Radcliffe Duncan, Oak Terrace Minn. University of Minnesota Medical School, Minneapolis, 1929, aged 32 on the staff of the Glen Lake Sanatorium, where he died, April 6, of tuberculosis.

Paul Gerhardt Sudhoff, Cincinnati University of Cincinnati College of Medicine, 1921, formerly medical director of the Hamilton County Home and Chronic Disease Hospital, aged 41 died, June 9.

Elizabeth Eldredge Wray-Howell ♂ Chester, Pa., Woman's Medical College of Pennsylvania, Philadelphia 1896 aged 63, died April 24, of rheumatic heart disease, myocarditis and endocarditis.

William Preston Hickman ♂ Harvey, La. Tulane University of Louisiana Medical Department, New Orleans 1908 aged 51 died, April 13, of cardiorenal disease, hypertension and arteriosclerosis.

Russell E Hawley ♂ Merrill Mich., Detroit College of Medicine and Surgery 1926 on the visiting staff of the Saginaw (Mich.) General Hospital, aged 36 died suddenly April 12 of heart disease.

Solomon H Barron, Hopewell Miss., Memphis (Tenn.) Hospital Medical College 1905 aged 63 died, May 9 in the Baptist Hospital Jackson, of hypertension and chronic myocarditis.

George Elliott Noggle, Chino Calif. Kansas Medical College Topeka 1895 member of the California Medical Association, aged 63 died, April 8 of adenocarcinoma of the cecum.

Lawrence Johnson Winder, Andalusia, Pa., Jefferson Medical College of Philadelphia, 1893, veteran of the Spanish American War, aged 69, died, April 22, of chronic myocarditis.

Fred Harrison, Gridley, Calif., California Medical College, San Francisco, 1905, member of the California Medical Association, aged 65, died, April 24, of endocarditis and influenza.

David Rice Gooch, Nolensville, Tenn., Vanderbilt University School of Medicine, Nashville, 1877, for many years member of the county school board, aged 82, died, April 6.

Tobias Higgins, Traphill, N C. (licensed in North Carolina in 1915), aged 62, died, April 13, in the Wilkes Hospital, North Wilkesboro, of coronary occlusion and arteriosclerosis.

Robert H Hunt, Gibson, Tenn., University of Nashville Medical Department 1872, Civil War veteran, for many years bank president, aged 90, died, April 6, in Humboldt.

May McKinney Palmer, Mercer Island, Wash., Cooper Medical College, San Francisco, 1899, aged 71, died, April 23, in the Stanford University Hospital, San Francisco.

Robert E Hughes, North Holston, Va., University College of Medicine, Richmond, 1909, member of the Medical Society of Virginia, aged 51, died, April 13, of pneumonia.

George Young Hunter ♂ Prosperity, S C., Tulane University of Louisiana Medical Department, New Orleans, 1891 aged 67, died suddenly, April 30, in Columbia.

Clyde Oscar Anderson ♂ Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1895, aged 65, died, May 18, of diabetes mellitus and coronary thrombosis.

John Walters ♂ Sewickley, Pa., Western Pennsylvania Medical College, 1897, on the staff of the Valley Hospital, aged 62, died, April 24, of cerebral hemorrhage.

Michael Roberson, Durham, N C. Medical College of Virginia, Richmond 1912, aged 51, died, April 30, of coronary sclerosis and pulmonary embolism.

James Porter Fuller, Modesto, Calif., Michigan Homeopathic Medical College, Lansing, Mich., 1872, aged 92, died, April 10, of chronic myocarditis.

Trusten Polk Peery, Marysville, Calif., Missouri Medical College, St. Louis, 1884, aged 78, died, April 16, of chronic myocarditis and acute nephritis.

Lillian Craig Randall, Rye, N Y., University of Buffalo School of Medicine, 1891, aged 77, died, April 17, of uremia and myocardial insufficiency.

Arthur Heinzelmann, Kansas City, Mo., Eclectic Medical University, Kansas City 1907, aged 58, died, April 4, of chronic nephritis and endocarditis.

Richard Hudson Beek ♂ Lakota, N D., University of Minnesota Medical School, Minneapolis, 1894, aged 66, died May 6, in Devils Lake.

George Samuel Bailey ♂ Hillsboro, N H., College of Physicians and Surgeons, Boston, 1899, aged 68, died, June 24, of angina pectoris.

Henry Charles Darby, Wilmot, Wis. College of Physicians and Surgeons of Chicago, 1883, aged 81, died, April 28, of coronary occlusion.

George W Westbrook, St. Louis American Medical College St. Louis, 1897, aged 74, died, April 13, in Maplewood, Mo., of heart disease.

Jacob F Roemer, Waukegan Ill., Hahnemann Medical College and Hospital, Chicago, 1891 aged 75, died, May 4, of heart disease.

Robert Ballard Davy, Hayward Calif., Jefferson Medical College of Philadelphia, 1868, aged 88, died, April 30, of myocarditis.

Hart M Boxley, Millersburg, Ky., Louisville Medical College 1901 aged 65, died, May 8, of cardiorenal disease and hemiplegia.

Mary Hobbs Iredale Earle, Cincinnati, Eclectic Medical Institute Cincinnati, 1891, aged 75, died, April 24, of intestinal obstruction.

Caleb W Bronson, Alameda Calif., Hahnemann Medical College San Francisco, 1884, aged 89, died, April 24, of arteriosclerosis.

Victor A. Bergeron, Kankakee Ill. Chicago Medical College, 1877, formerly a druggist aged 82 died May 6.

Frank A Noyes, Biggsville, Ill. (licensed in Illinois in 1878), aged 86 died, April 4.

B M Doyle, Knoxville, Tenn. (licensed in Tennessee in 1889) died April 24.

Bureau of Investigation

"MEDICAL ECONOMICS"—A HANDBOOK OF NOSTRUMS

For some time physicians throughout the country have been receiving each month through the kindness (?) of some dealer in medical or chemical supplies a periodical called *Medical Economics* with the subtitle "The Business Magazine of the Medical Profession." It has previously been called by THE JOURNAL in editorial statements a "throw-away periodical." It has apparently little, if any, paid circulation although it is stated that the price is 25 cents a copy or \$2 a year. It should be apparent to any one after glancing through the pages of any recent issue that this publication depends for its income and its circulation on the advertisements of great numbers of nostrums which from time to time have been investigated and rejected by the Council on Pharmacy and Chemistry of the American Medical Association. Following is a list of non-accepted preparations advertised in the issue of June 1936 with brief statements as to their records as far as the files of the Council on Pharmacy and Chemistry are concerned.

Fellows Syrup —Rejected by the Council twenty years ago because it was held to be a semisecret unscientific preparation—an affront to sound therapy—exploited by means of extravagant and misleading statements.

Antiphlogistine —A preparation which has been exploited for more than a quarter of a century with unwarranted and extravagant claims. In 1929 the Bureau of Chemistry of the American Dental Association published a report stating that the wonderful effects of the hygroscopic powers of Antiphlogistine are so manifestly absurd as to be unworthy of further refutation.

Argyrol —Once included in N N R but omitted in 1928 because of the manufacturer's refusal to comply with the Council's rules on claims and nomenclature.

Neobovimine with Malt and Iron —In 1931 the Council declared Neobovimine unacceptable for N N R because the information in regard to its composition is inadequate because the therapeutic claims are unwarranted and because the combination was considered unscientific.

"Taxol" —An unscientific mixture claimed to contain the total extract of the intestinal glands, biliary extract and lactic ferments with agar agar. Has not been considered by the Council.

Eskay's Neurophosphates —An irrational mixture marketed with unwarranted therapeutic claims under an objectionable name. Rejected by the Council twenty years ago.

Fescol Tablets —A dosage form of ferrous sulfate encased in U S P A which has not been considered by the Council.

Oxo-ate-B —A proprietary uninforming name for calcium ortho-oxo-benzoate. The isooxybenzoates were omitted from N N R in 1932 because of lack of evidence for their usefulness.

"U S T (Tilden)" (formerly "Uterine Sedative Tonic") —Unscientific mixture of obsolescent drugs, reminiscent of the female weakness cures exposed many years ago.

Ovaltine —Reported unacceptable by the Committee on Foods in December 1931.

Farastan —A cinchophen derivative which the Council rejected in 1930 because it was held to be an irrational preparation marketed with unwarranted therapeutic claims.

Oroferrin —Omitted from N N R in 1929 as an unscientific and superfluous mixture.

Vihurno —A viburnum preparation of the type exposed by the Council more than twenty years ago.

Tablet Stanno-Yeast —Probably a tin and yeast mixture. Has not been considered by the Council.

Pancrothin Tablets —Appears to be a modification of an old Reed and Carnrick preparation, the composition of which has been held to be essentially secret and the claims for which are extravagant and unwarranted.

Lorate —A fanciful name for a sodium perborate mixture. Has not been considered by the Council.

Nupercainal —An unaccepted dosage form of a Council-accepted anesthetic.

Calmitol —Stated to be a solution of Chloro-Camphoric aldehyde slightly iodized combined with menthol and a small amount of Laevo-Hyoscyne Oleinate in an ether alcohol chloroform base. Has not been considered by the Council.

Mu-col —Rejected by the Council in 1913 for conflict with Rules 1 4 6 8 and 10.

Kao-Mincin —Has not been considered by the Council.

Sal Hepatica —In 1914 the Council published its condemnatory report on this preparation in order that physicians may know the extent to which they have been made to act as advance agents for "patent medicines." Today Sal Hepatica is a full fledged patent medicine.

Ocey Crystine —Has not been considered by the Council.

"Alkalol" —Examined by the A M A Chemical Laboratory in 1915. In 1913 was the subject of the following comment by THE JOURNAL:

The polypharmacy represented by such a mixture is absolute non sense—the really useful ingredients are obscured by the useless shrunken which surround them.

"Aurocein" —Claimed to be "For the Gold Therapy of the Arthritides." Has not been considered by the Council.

"Taurocol" —A preparation to which the Council refused recognition in 1915 because of objectionable claims and composition.

"Unguentine" —Not considered by the Council. Reported on unfavorably by the A M A Chemical Laboratory in 1909.

"Hepvise" —A mixture of hepatic extract, insulin free pancreatic extract and mistletoe for high blood pressure. Has not been considered by the Council.

"Aspir Vess" —Bromo-Vess and Cinsa Vess —Effervescent mixtures of well known drugs which have not been considered by the Council.

"Burnham's Soluble Iodine" —Found unacceptable for N N R in 1933. A semisecret preparation marketed with extravagant and unwarranted therapeutic claims.

"Tablet Alukalin" —Has not been considered by the Council.

"Kaha" —A Battle Creek Food Co product comprising karaya gum plus yeast extract. Has not been considered by the Council.

"Ophthalmic Solution No 2 (DeLeaton)" —Not considered by the Council.

"Dionol" —The "Glorified Petrolatum" about which THE JOURNAL in 1918 wrote as follows: If one takes the word of the manufacturer, the therapeutic possibilities of Dionol are apparently limited only by the blue sky.

"Aluocol" —Rejected by the Council in 1928 because of conflict with the rules regarding nomenclature and therapeutic claims.

"Vince" —A sodium perborate preparation which has not been considered by the Council.

"Glyco-Thymoline" —In 1914 the Council called it a typical example of a patent medicine advertised to the public through the doctors. At that time in conflict with Rules 1 4 6 8 and 10.

"Stannoxyol" —A tin preparation for boils etc. which THE JOURNAL criticized in 1920 because of extravagant claims.

Gardner's Syrupus Acidi Hydriodici —Under the English name Gardner's Syrup of Hydriodic Acid this preparation was rejected by the Council in 1908 because of unwarranted claims.

"Gude's Pepto-Mangan" —More than twenty years ago the Council called attention to the unwarranted claims made for this preparation and to the manufacturer's attempt to exploit the product to the public.

"Aminophyllin Phenobarbital and Aminophyllin Potassium Iodide (Battle)" —These aminophyllin mixtures have not been considered by the Council.

"Micajah Medicated Wafers" —Found unacceptable by the Council in 1919 because the composition is essentially secret, the name is not indicative of composition, the therapeutic claims were exaggerated and unwarranted and because the product was advertised indirectly to the public.

"Absorbine Jr" —A patent medicine which has not been considered by the Council. See Nostrums and Quackery.

"Iododin (Iodinized Oil Compound)" —Has not been examined by the Council.

"Saraka" —Contains an agar agar substitute plus the laxative drug frangula. Introduced under the name "Normacol" as an ethical proprietary and now advertised directly to the public.

"Evac-u-gen" —Has not been considered by the Council.

"Man Na Gluconate" —A colloidal manganese sodium gluconate preparation. Has not been considered by the Council.

"Mazon" —A preparation of semisecret composition which has not been considered by the Council.

"Endo-Antrone" —Stated to be "a standardized anterior Pituitary like preparation of sex hormones." Has not been considered by the Council.

"Viscysate" —A mistletoe preparation which has not been considered by the Council.

"Sanmetto" —In 1915 the Council called it "a secret nostrum the exploitation of which is an invitation to haphazard uncritical therapy and a menace to public health."

"Uvursin" —An oral diabetic treatment reported on by the Bureau of Investigation.

"Kondremul" —Rejected by the Council in 1933 because of objectionable claims and name.

"Ceanothyn" —First rejected in 1926. Rejection reaffirmed in 1930. Claims unwarranted. Evidence for the usefulness of the product inconclusive.

"Ergoapiol (Smith)" —An unscientific shotgun mixture of drugs having widely different therapeutic effects. Rejected by the Council in 1914.

"Cystogen" —A therapeutically suggestive name applied to the well known drug methanamine. Rejected by the Council in 1914.

"Ortho-Gynol" —Has not been considered by the Council.

"Cremo-Carbonates" —Has not been considered by the Council.

The physician who believes the majority of these advertisements and prescribes the preparations listed departs far afield from the tenets of scientific prescribing. And he practices an uneconomical "medical economics." He serves as an agent for

the introduction to his patients of unaccepted, trade-name medicinal preparations. Patients obtain the first purchase on his prescription, thereafter they buy these preparations over the counter, frequently to their own detriment. Thus the doctor becomes an agent for introducing these preparations to patients, who in turn urge them on their self-prescribing friends. In many of the trade packages, accompanying circulars and advertising matter will be found which has the obvious purpose of inducing self medication.

The manufacturer of legitimate medicinal products who associates himself with nostrums such as are promoted through the pages of *Medical Economics* is also figuratively cutting his own throat. Physicians interested in the advancement of scientific medicine and in the welfare of their patients, as well as in their own welfare, will do well to limit their prescriptions for medicinal agents to those items which are included in the U. S. Pharmacopeia and in New and Nonofficial Remedies.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

HEAT OR COLD FOR PAIN OF APPENDICITIS

To the Editor—What is the best method to relieve pain and will off infection in acute appendicitis and also in acute mastoiditis? Is it better to apply the ice bag or the hot water bottle to the region of the mastoid or the region of the inflamed appendix? Why is it that some authorities claim that it is better to use heat while others say to use ice? When is the right and proper time to use one or the other? If either ice or heat is used should the heat or ice be continuous or should it be applied off and on—an hour on and about fifteen minutes to half an hour or so off? What is the best usage? I was taught in cases of acute appendicitis with a child or an aged person to apply the hot water bottle, while with all others apply the ice bag. I was also taught to apply the ice bag continuously. Please omit name. MD New Jersey

ANSWER—The pain of acute appendicitis is seldom severe enough to require morphine. In the presence of acute abdominal pains suggestive of appendicitis it is best not to give morphine or any other powerful opiate until the diagnosis is made for fear of disguising the picture and delaying diagnosis. If the patient must be observed for a time before the diagnosis can be made and if pain must be relieved to a certain extent, from 0.03 to 0.065 Gm. of codeine by mouth is an excellent sedative. Often acetylsalicylic acid, aminopyrine or sodium bromide will give sufficient sedative reaction to control the pain of appendicitis until the diagnosis is made. In the case of acute mastoiditis the nature of the infection is more evident and the relief of pain more imperative or more logical. Morphine, codeine or one of the milder sedatives can be safely used here.

The physiologic action of the ice bag or of the hot water bottle is practically the same. Both cause a localized hyperemia but the thermic units, whether heat or cold, are soon dispersed by the blood stream in the wall of the abdomen. Thus many authorities do not believe it makes much difference whether an ice bag or a hot water bottle is used. Many doubt if they have any influence in localizing or "walling off" infection in acute appendicitis. More relief of pain seems to be given by the use of the ice bag in acute appendicitis than of the hot water bottle.

LOSS OF HAIR DUE TO THYROID DEFICIENCY

To the Editor—I have a healthy patient aged 27, weight 155 pounds (70 kg.) whose symptoms are falling of the hair, irregular delayed menstrual period and gradual increase in weight. The hair is thin and not patchy. The falling of the hair is pronounced around menstrual time. She has had two pregnancies and all her symptoms date back to the first pregnancy. Could you suggest any procedure to determine the cause if due to endocrine disturbance other than basal metabolism which I plan to get? Please omit name and address. MD Ohio

ANSWER—The first procedure which is obviously being planned is to determine the basal metabolic rate. The clinical symptoms mentioned in the query point to the thyroid rather than to any of the other endocrine glands and they should be helped by thyroid therapy. It is possible though not certain, that other tests may later be indicated such as x-ray examination of the thyroid, blood sugar determination and sugar tolerance tests.

URETHRITIS WITH PHOSPHATURIA

To the Editor—I have under my care at present a man aged 25 who is suffering from a chronic urethritis. He has a persistent phosphaturia. He has been receiving fairly large doses of sodium acid phosphate with no help. Will you kindly let me know the significance of this condition and also any suggestions you may have for its treatment?

MILOSH KASICH, MD New York

ANSWER—There is considerable difference of opinion as to the clinical significance of phosphaturia. Although some urologists believe that it can be the cause of irritation, in the majority of cases its finding is of no clinical importance. It is doubtful whether phosphaturia alone is ever the cause of chronic urethritis. It is conceivable that precipitated phosphatic material might cause some irritation of an inflamed urethra, but hardly sufficient to produce a discharge. The persisting urethritis is probably due either to infection in the prostate gland and seminal vesicles, a stricture, or a follicular infection in the urethra.

The coincidence of phosphaturia and chronic urethritis is not uncommon. Patients occasionally are observed with both these conditions who become well following acidification of the urine. However, it has not been proved that overcoming phosphatic precipitation in the urine by acidification is necessarily the factor that aids the urethritis. In acidifying the urine it is advisable to keep a record of the hydrogen ion concentration in order to determine the efficacy of medication employed. It is well known that acidification of the urine frequently has an inhibitory effect on bacterial growth and that infection sometimes may be overcome by this comparatively simple procedure. In order to prevent bacterial growth it is necessary that the pH of the urine be brought down at least to a level of 5.4. Precipitation of phosphatic crystals usually occurs when the pH is no longer neutral or is slightly alkaline, and slight acidification with a pH less than 6, will usually cause phosphatic crystals to disappear. For the purpose of acidifying the urine, ammonium chloride given in enteric coated tablets will be found to be more efficacious than acid sodium phosphate.

IMMUNITY OF NEW BORN TO RESPIRATORY INFECTIONS

To the Editor—Please comment about the immunity of the newborn to respiratory infections. I am more interested in susceptibility of the newborn and infant to infections of the upper respiratory tract—the common cold, rhinitis, nasopharyngitis, tonsillitis, otitis media, bronchitis—than to the pneumonias. Is the newborn infant slightly susceptible or even susceptible at all to any of the respiratory infections? Comment briefly about the loss of natural immunity to respiratory infections as age advances. MD Texas

ANSWER—The new-born and the young infant seem to enjoy at least a relative immunity to infections of the upper respiratory tract. It has been observed that the incidence of such infections is four times greater at the twelfth month than at the third. Infants who have passed their first six months seem more susceptible to infections of the upper respiratory tract than those of the previous age period. This immunity in the young infant can be explained only by the assumption that antibodies in variable quantity are present in the body of the infant. The mother probably confers immunity to the infant. The best objective example of this early natural immunity is shown by the Schick test for diphtheria. In the first few months of life it is negative in 85 per cent of the cases. Toward the end of the first year the immunity has diminished so much that the Schick test is negative in only 10 per cent of the cases examined. On clinical grounds alone one would assume that the same degree of immunity holds good for diseases of the upper respiratory tract, though in the latter group the point cannot be proved as in the case of the susceptibility to diphtheria by use of the Schick test.

There are other factors such as the vague expression "the child's constitutional state." It appears that some children are better antibody producers than others. It has been observed that infants who appear fairly well developed and not debilitated by previous disease or nutritional disturbance may nevertheless show a markedly diminished immunity against infection. This applies to infections of the upper respiratory tract as well as to other infectious processes that attack young infants.

The season of the year also seems to affect the incidence of infections of the upper respiratory tract. Every clinician knows that infections and the high mortality rate and complications resulting from them are greater during the winter months than during the warmer season of the year. While these facts of seasonal variation are well known nevertheless it is difficult to offer an adequate explanation.

The nutritional status of the infant is an important contributing factor in establishing his immunity to infections of the upper respiratory tract. In healthy babies intercurrent infections of the upper respiratory tract take a moderate and short

course, whereas in those who have been improperly fed or have previously suffered from alimentary disorders the course is more protracted and severe. In a breast-fed infant, as a rule, there is greater resistance to infection, and if it does occur it runs a milder course.

A well balanced, well regulated diet tends to produce an optimal state of immunity. In the case of the artificially fed infant this obviously refers to the correct quantity and quality of the various food substances, properly balanced. It has been stated, and it is probably correct to say, that the vitamins A, B, C and D not only play an important part in nutrition but also tend to increase the immunity of the infant against infections, including disorders of the upper respiratory tract.

So far as the loss of natural immunity in respiratory infections with advancing age is concerned, one can only say that in addition to the loss of natural immunity there are such external factors as overcrowding in ill ventilated homes or institutions, exposure to infections, and the effect of cold and chilling on the body surface. We must also consider the increase in susceptibility to allergic factors, such as food, pollen and dust-laden air, animal emanations, and a host of other things that tend to cause allergic response. Nowhere are these reactions more marked than in the mucous membranes of the upper respiratory tract.

URTICARIA

To the Editor—A white man aged 44 married a farmer, complains of hives which first appeared about three years ago and are present from the beginning of fall through spring. The hives usually appear while he is in the house and disappear sometime after he goes outside. The rest of the history the physical examination urinalysis and blood count are negative. The patient was found to be sensitive by intradermal test to cattle hair horse hair wheat, potatoes and milk. Elimination of foods containing the latter three articles from his diet was of no avail and the patient cannot change his occupation in which he comes in close contact with both cattle and horses. A course of antigen for desensitization was given and the hives became smaller, did not last as long and did not itch as severely as before the treatment. However they occur as frequently as before. I am now giving the patient the continuation vial for continued treatment. Can you give me any suggestion as to further treatment? Please omit name and city.

M D, Illinois

ANSWER—It is suggested that the injections already started be continued for perhaps a month or two. In addition, it would be wise to try systematic elimination diets, irrespective of the skin tests. It is well known that in most cases of urticaria skin tests are not successful, as they are either positive with no clinical basis or negative to foods that really do bring on the attacks. In only about 25 per cent of instances (the figures vary with different workers) do the skin tests in urticaria correlate with the clinical observations. The percentage of positive skin tests in hay fever is about 95, in bronchial asthma perhaps 75.

Elimination diets may be carried out in several ways. One method is to eliminate one set of foods at a time, for example, all meats are forbidden for one week, then all fish, then fruits, vegetables, spices, nuts, cereals, eggs, milk, and so on during successive weeks. Another way is to start with milk and cream alone for two or three days and then add one food at a time. A third way is based on such diets as prescribed by Rowe in his book on food allergy. These diets are numbered 1, 2 and 3 and the patients are given those foods which are least likely to cause the urticaria. Eggs, wheat and milk are the most common offenders and are therefore kept out of the diet until all other foods have been tried. A record of changes in diet should be kept and from four to seven days should be required to see whether adding or subtracting a food has any clinical effect.

While most cases of urticaria are due to foods, some come from contact with certain substances particularly silk, horse hair, wool and certain dyes used in garments. These contacts should be looked into. Removal of a hair mattress has cleared up some cases. Substitution of rayon for silk has helped others. Drugs too may be responsible, as many cases have followed the use of such coal tar products as acetylsalicylic acid or aminopyrine. Quinine, barbiturates and other drugs have also caused trouble. Drugs are more apt to cause angioneurotic edema than ordinary urticaria. It would be wise to stop the use of all drugs if any are being given.

Other methods of treatment for urticaria may be tried. Autohemotherapy is favored by some. Withdraw 10 cc of blood from an arm vein and inject the blood at once intramuscularly into the buttocks. Vaccines have been tried calcium by mouth or intravenously and thyroid extract have been used. Most of these are only fairly successful, if at all. It is, of course, necessary to build up the patient's resistance as much as possible and to have him avoid all things that make him more nervous and therefore more susceptible to pruritus.

EFFECTS OF TUBERCULIN AND FOCAL REACTIONS

To the Editor—Having diagnosed pulmonary tuberculosis in a youth, aged 19 years, I thought I had better have the sputum of all the members of the family tested as well as do the intradermal tuberculin test on all. On inserting the needle intradermally in the forearm of the brother (20 years of age) I noticed the solution shoot out from the needle where it joins the bulb. No wheal was raised hence I sterilized another needle and proceeded to do the intradermal injection about 1 inch above the other point of injection. This was done on Saturday at 3 p. m. Sunday at 10 a. m. the patient returned complaining of a lump in the axilla. Around both points of injection was a flat area of erythema about one-half inch in circumference. The swelling in the axilla was soft and probably was an axillary gland inflamed. The patient complained of chilly sensations but had no fever. What worries me is: Did I give too much tuberculin unknowingly (New York Board of Health tuberculin) with a severe reaction? Did I inadvertently inject contaminating pyogenic organisms? Does the axillary enlargement indicate an existing tuberculous disease (rather than infection)? The chest has been negative. If the axillary swelling begins to fluctuate would you suggest incision and drainage or aspiration?

HENRY ROSNER M.D. Brooklyn

ANSWER—It does not seem probable that the axillary swelling was due to tuberculin, since such a short time elapsed between its administration and recognition of the swelling. Usually there is little or no reaction even at the site of injection in less than twenty-four hours. It would also seem unlikely that pyogenic micro organisms introduced so recently would result in the axillary condition. The development in the axilla is probably a coincidence or was preexistent rather than the result of tuberculin. If the swelling proves to be due to involvement of an axillary lymph node and fluctuation is elicited, aspiration may suffice. Examination of the aspirated material by smears, cultures and animal inoculation should aid in the final diagnosis.

Large doses of tuberculin introduced subcutaneously may cause focal reaction, that is, at the site of an area of disease some inflammation appears. In the case of superficial lymph nodes, such as those of the axillary group, enlargement and tenderness may be experienced. However, if the standard initial dose of tuberculin was used and even if all of both injections was introduced intracutaneously, it is most unlikely that such a reaction would result.

PREGNANCY IN HEART DISEASE

To the Editor—A white woman, aged 24 married had rheumatic fever at 6 but no subsequent attacks. Cardiac residuals consisted of chiefly aortic insufficiency (the mitral valve seems to be intact). The heart is fairly well compensated. The patient has no dyspnea or cyanosis but occasionally suffers pseudo-anginal pains lasting several hours and occurring only when she is at rest. No headaches occur she is rarely dizzy and she has no fainting spells. An appendectomy has been done and one ovary was removed for a cystic condition. She stood the operations well. What do statistics show as to the length of life in such cases? The patient is desirous of having a child. Should she be permitted to do so? Kindly withhold name.

M.D. New York

ANSWER—It is of the utmost importance in answering this query to know how much aortic insufficiency there is, how big the heart is, what the blood pressure levels are (both systolic and diastolic), the site of the pseudo-anginal pain, and whether or not it is simply the heart ache of neurocirculatory asthenia, as it probably is.

Assuming that the mitral valve is normal or at least not deformed to any appreciable degree, the following prognosis and suggestions may be made for each of three degrees of aortic regurgitation.

1 For very slight aortic regurgitation in which the heart will be little if at all enlarged and the blood pressure normal or but slightly changed, the prognosis will probably be good for many years to come, and in the absence of recurrent rheumatic infection or subacute bacterial endocarditis the patient may live the full length of life and go through several pregnancies with safety.

2 If the aortic regurgitation is of moderate degree with slight to moderate cardiac enlargement and a fairly full pulse, but not one of full blown water hammer character, the prognosis will not be so favorable. Life will probably continue for a number of years, but it seems likely that heart failure and death may occur sometime between ten and twenty years from now, other things being equal. It may be all right to allow such a patient to go through one pregnancy carefully watched.

3 In a patient with a high degree of aortic regurgitation, a much enlarged heart, and a water hammer pulse, a very full pulse pressure (such as with a systolic blood pressure of 140 or 150 and a diastolic pressure of 20 or 30) the prognosis is unfavorable, and it is possible that the patient may succumb in the next ten years from heart failure, from extension of the

heart disease or from subacute bacterial endocarditis. Such a patient should not be allowed to go through pregnancy.

If at the present time there is real angina pectoris or any evidence of congestive failure, the prognosis is still more unfavorable and the duration of life the matter of a few years at best.

OTOSCLEROSIS

To the Editor—I am 47 years old. Twenty years ago I discovered that I was not hearing as well as I should. From then on deafness has descended on me till now I find it a great burden in my life as a general practitioner. Some say it is otosclerosis and others nerve deafness. Probably it is both. The high notes are especially bad. I use a telephone aid and a Western Electric hearing aid. My hearing is much better in a moving auto and in a dance hall. I can hear better than most of my partners in fact, for a few hours while dancing I am in a new world with the blight of deafness removed. Is there not some clue for relief in the fact that my hearing is better in the circumstances mentioned? Is there anything you can recommend to help or at least to prevent further progress of this deafness? Is there any use in going to one of the great clinics for examination or treatment? I can manage if I do not get worse. Please omit name and address.

M D Manitoba

ANSWER—From the description given, this is probably a case of otosclerosis in which there is also involvement of the cochlea, so that the high tones also are affected. Many patients with otosclerosis have the so-called paracusis Willisii, in that they apparently hear better in a noisy environment. This is probably due to the fact that the otosclerotic patient does not hear the low tones, whereas the hearing individual who is conversing with him is masked for low tones by the surrounding noises and therefore raises his voice in intensity so that the individual with impaired hearing can better understand. He therefore thinks he is hearing better in a noise. If a thorough examination of the hearing function has been made, there would be no object in repeated examinations so far as a guide to treatment is concerned, for unfortunately there are no therapeutic measures that are of any avail in otosclerosis. On the other hand, if the bone conduction is normal or prolonged, the individual is often greatly benefited by the use of an electrical hearing aid, particularly one that has an attachment for application to the bone of the mastoid region.

SEPTICEMIA AFTER ABORTION

To the Editor—I have a patient who has developed a septicemia following incomplete abortion. Would you please give me information on the treatment of septicemia? This patient has a red cell count of 4,950,000, a hemoglobin of 70 per cent and a white cell count of 10,500. She feels quite well except for the chills and she is taking nourishment quite well. She has a severe headache beginning just before and continuing through the duration of the chill. A chill lasts about fifteen minutes. This condition developed about two weeks after the abortion started. She states that intervention was not done and I have reason to believe that she has done nothing to bring on abortion. Please omit name.

M D North Dakota

ANSWER—From the history of the case it does not appear certain that the patient has a septicemia. Nearly always when septicemia occurs in a case of incomplete abortion the infection starts within a few days following the abortion. Furthermore, this patient's subjective symptoms apparently are not disturbing except for the chills. Another unusual occurrence in this case is the normal red blood count, white blood count and hemoglobin. Nearly always in cases of septicemia there is a secondary anemia and a definite leukocytosis. No information is given concerning the temperature, the urinary examination and blood cultures. The history of a late onset of chills in this case should make one suspect pyelitis or thrombophlebitis. A catheterized specimen of urine should be obtained and it should be examined microscopically.

Treatment in this case should be along general lines. The patient should have abundant fresh air and ample sunlight. She should be given large quantities of fluids and fruit juices. If the urine contains many pus cells, large amounts of alkali should be given for a few days and then large amounts of acid should be given instead. Solution of posterior pituitary, 0.5 cc three times a day, helps in some cases. If the uterus is not well involuted, a half teaspoonful of fluid extract of ergot should be given by mouth four times a day for a few days. Nourishing food, of course, should be given. Attention should be paid to the bowels and bladder. If the patient cannot sleep sedatives should be given. The only indication for intra-uterine manipulation is hemorrhage that cannot readily be controlled by ergot and pituitary extract. Even if septicemia is definitely present there is no specific therapy. In some cases antistreptococcus serum is of distinct help. Large amounts of alcohol in the form of wine help others. Blood transfusions in amounts between 250 and 300 cc. are of great benefit even in cases in which there is not much anemia.

HAY FEVER RESORTS IN MAINE

To the Editor—I should like information regarding a good hay fever resort in Maine. The resort will have to be near a point where a patient could have hospital facilities if necessary and medical care.

EDWARD C. ALBERS, M.D., Champagn, Ill.

ANSWER—Any city in the vicinity of the Rangeley Lakes in the northern end of Maine will be found satisfactory for a ragweed hay fever sufferer. Calais, Fort Fairfield and Houlton, in Aroostook County have first-class hospital service. The latter place has two hospitals. It is advisable to avoid the Maine coast unless perhaps at Eastport, where the ragweed pollen concentration is less than at other points on the coast. The total pollen count for Eastport in 1935 was 280. There were only four days on which the pollen count exceeded 25 granules per cubic yard of air. The count at Upper Dam in the Rangeley Lakes area was 165, with only one day above 25. Conditions in northern Maine are even better than at Upper Dam.

MAPHARSEN IN SYPHILIS

To the Editor—A carpenter aged 42 weighing 160 pounds (73 Kg.) incapacitated for a month to six weeks because of what he thought to be rheumatism complicated by measles seen June 13, 1935 had a typical secondary papular syphilid with a four plus Wassermann reaction. The eruption had appeared from two and a half to three weeks previously. He had been exposed (at which time gonorrhea also was contracted) in March which was a full three months earlier. Examination revealed a penile scar chancre, which had been treated locally, edema of the foreskin and a gonorrheal discharge. The vascular and renal systems and the eyes were normal. No positive neurologic signs were found. It was decided to place the patient on the therapeutic regimen outlined by the League of Nations Committee of Experts (THE JOURNAL, April 11, 1935, p. 1329). The patient could be seen only once a week, so the arsenical chosen was mapharsen 0.06 Gm being used in all but the initial dose. The bismuth preparation used was bismuth salicylate in oil, 2 grains (0.13 Gm.). Potassium iodide was given by mouth during the bismuth courses. To date the following has been given: Eight injections of mapharsen followed by four weekly injections of the bismuth preparation then six injections of mapharsen and I have just finished the sixth and last dose of the second course of the bismuth preparation. The serologic reactions after both arsenical courses and the first bismuth course is Wassermann four plus and Kahn three plus. A spinal fluid examination at this time revealed the Wassermann reaction two plus, globulin slightly increased and colloidal gold 3332211000. The clinical response to treatment has been excellent, the patient being able to resume work after the second dose of the arsenic preparation. At present he states that he feels better than he has in ten years. Aside from the original dose of mapharsen when a marked Herxheimer reaction occurred, all treatment has been very well tolerated. There are no neurologic changes. Please advise whether I am justified in carrying out the plan of treatment I have started or should this be altered in any way. Would tryparsamide be a better arsenical to use in this case in view of the spinal fluid examination and if so how would it fit into the scheme of treatment? Please omit name and address.

M D, Kansas

ANSWER—Mapharsen is a trivalent arsenical compound, chemically meta-aminoparaxydroxyphenylarsine oxide, which has been recently tested out in experimental trypanosomiasis and human syphilis. The first report by Foerster and his associates made on the basis of a clinical study on eighty patients treated with 2,117 injections of the drug indicated that mapharsen was a potent antisyphilitic agent and that further clinical trial was justified. In nearly all the cases of early syphilis the Wassermann reaction of the blood serum was reversed to negative. Return to a positive reaction occurred in half the cases and was found to be associated in five with abnormalities in the spinal fluid. The drug was well tolerated by nearly all the patients in properly adjusted dosage. Mild gastro-intestinal symptoms occurred in some, jaundice developed in four cases, and renal symptoms were observed in four others. Other observers have also had the impression that the clinical results were comparable with those of the arsenphenamines. The value of mapharsen in neurosyphilis cases is still undecided and for the present Lorenz and Bleckwenn, who have used the drug for more than two years, state that it is not to be recommended in these cases. As the spinal fluid in the present instance is positive, it would seem to be wiser to substitute tryparsamide with proper visual control. Courses of tryparsamide should alternate with heavy metal therapy in the effort to obtain a reversal of the positive spinal fluid. The following references should be consulted:

Foerster, O. H., McIntosh, R. L., Wiedler, L. M., Foerster, H. R., and Cooper, G. A. Mapharsen in the Treatment of Syphilis. A Preliminary Report. *Arch. Dermat. & Syph.* 32: 868 (Dec.) 1935.
Gruhatz, O. M. Mapharsen (Arsenoxide) in the Therapy of Experimental Syphilis and Trypanosomiasis. *Arch. Dermat. & Syph.* 32: 848 (Dec.) 1935.

Mapharsen stands accepted by the Council on Pharmacy and Chemistry of the American Medical Association (THE JOURNAL, January 18, p. 214).

RECTAL GONORRHEA

To the Editor—I have under my care a woman of 30 who for the past year has complained of vague abdominal pains and a daily rise in temperature of low grade type, 99 to 100 with no increase in pulse and no loss in weight. The external physical examination is negative, the blood Kahn reaction is entirely negative. The urine is normal. Cervical smear is positive for gonococci for which I have been treating her for five weeks. Recently I made a proctoscopic examination and found the rectal mucosa to be very hyperemic and it bled on the least manipulation. At the upper pole of the rectum I discovered what appeared to be free pus, with no apparent sac. On gram stain I found intracellular gram negative diplococci, identical with the gonococci. Now this is apparently a case of rectal gonorrhea also. I should like to know whether the rectal condition could be responsible for the abdominal pains (mild gnawing sensation). The pelvic examination revealed free adnexa. Also is there a standard accepted method of treatment for rectal gonorrhea? How could the gonococcus gain access to the rectum unless during the act of wiping while at stool? There is no history of perverted intercourse. Please omit name. M D Illinois

ANSWER—Perverted sexual intercourse is a frequent cause of gonorrheal proctitis. It is difficult and often impossible to obtain a history of perversion, particularly if this has occurred but once. It may also occur in women who have been infected with gonorrhea and who are careless about their personal hygiene. Infected enema points have been held responsible in some instances. In some cases it may be quite impossible to determine the method of infection.

Gonorrheal infection of the rectum rarely causes gnawing sensations in the abdomen, and in a situation of this kind one should look elsewhere for the cause of abdominal pain. In some of the cases there are no symptoms and in others there is a sensation of burning and smarting, as well as tenesmus.

Treatment is best carried out by rectal irrigations with silver nitrate in the strength of 1:2000. The solution should be made up with water free of chlorine. Application of silver nitrate in the strength of 1 or 2 per cent is very effective. If the silver nitrate produces too much irritation, one may use preparations such as strong protein silver, 5 per cent, or mild protein silver, 5 per cent.

INOCULATION AGAINST TYPHOID IN MAN AND
RABIES IN DOGS

To the Editor—As the family and I have traveled widely each summer for many years we have taken an immunizing series against typhoid and paratyphoid every four years. Is it necessary to continue doing this indefinitely or have we probably developed a permanent immunity by now? If possible I should like an answer to another question not strictly medical but it seems to me rather important. A year ago we adopted a dog and had him get an immunization against rabies. The veterinary surgeon who gave it said that it should be repeated annually. Can you tell me whether that is necessary or was he merely looking for an annual fee? I think all dog lovers should be informed on this point and would greatly appreciate an answer if you can give it. ROBERT W. SHEARMAN M.D. Brooklyn

ANSWER—Unquestionably the injections of vaccine will have produced a degree of immunity. It is conceivable, however, that a massive infection might overwhelm the resistance and consequently it might be safer to repeat the immunization if the exposure to infection seems dangerous.

The single inoculation of antirabic virus used for dogs confers immunity probably in many instances not exceeding a year. There have been some failures noted in shorter periods. It is a good precaution, therefore, to have the dog immunized each year.

PATHOLOGY OF OPIUM ADDICTION

To the Editor—What is known to date of the blood chemistry and tissue pathology gross and microscopic of chronic opium addiction? Needless to say we in China are in constant contact with this and I am interested in fitting our treatments to the needs with the hope that better results may follow.

FREDERICK G. SCOVILL, M.D. Tsining Shantung China

ANSWER—Blood chemistry in chronic opium poisoning when individuals are stabilized on their drug of addiction is set forth in the volume "Opium Addiction" published by the American Medical Association in 1929-1930. The volume consists of a reprint of articles by various authors reporting on studies conducted by the Philadelphia Committee for the Clinical Study of Opium Addiction (Archives of Internal Medicine, Volume 43-44). These reports show the following to be normal: blood sedimentation rate, fragility of the red cells, clotting time, viscosity of whole blood, oxygen content, red cell count, white cell count, differential and hemoglobin, cell volume, Wassermann reaction (subsequent experiences have shown that in some instances the blood Wassermann and Kahn reactions

have shown differences during addiction and following withdrawal), specific gravity of blood and plasma, plasma refractive index, dry matter of the blood and plasma, plasma p_n , carbon dioxide capacity of the plasma, serum conductivity, blood sugar, blood urea, creatinine and uric acid, blood chloride, blood calcium, and blood magnesium.

The accepted blood changes that take place during the abstinence period of addiction are blood concentration, leukocytosis, hyperglycemia, hyperlacticacidemia, and decrease in inorganic phosphorus content of the plasma, and slight rise in blood cholesterol, in unrelated form.

OBSTRUCTION OF CERVIX

To the Editor—A woman aged 35 was curetted in the fall of 1932 for the frequent passing of blood and accompanying pain. A diagnosis of endometrial hyperplasia was made at that time. She was completely relieved for a period of three months when the old symptoms reappeared and in addition at each period a terrific odor appears and remains for about two days following cessation of the period. The period is of four days duration with few clots and moderate in amount. Between periods she occasionally has pain in the lower quadrants of the abdomen and passes small gobs of blood. She has been to several clinics without relief. She has taken courses of theelin amniot and so on without relief. Smears are negative. Hanging drop smears are negative and there are no vaginal irritations, signs or symptoms. There is no other body change. What is the most plausible diagnosis? Would another curettage be advisable? Is there a possibility of a sponge having been left in the uterus? The uterus tubes and ovaries appear normal to digital examination. Please do not publish my name. M.D., Minnesota.

ANSWER—The absence of symptoms for three months following a diagnostic curettage, together with the clinical picture related, indicates possible obstruction in the cervix. Cervical strictures are relatively common and by their interference with the free flow of uterine secretions may give rise to the symptoms which the patient presents. A careful study of the cervical canal under anesthesia is in order, together with thorough dilation and curettage of the uterus.

It is unlikely that a foreign body was overlooked at the time of the previous curettage.

If, at operation, it should be proved that there is no cervical obstruction, the patient has hyperplasia of the endometrium as a result of dysfunction of the ovaries. The subsequent course will be most interesting.

FUNCTIONAL TIC

To the Editor—A white woman aged 45 complains of a muscular twitch in the back on the right side over an area corresponding to the rhomboideus major. This condition began in August 1932 and while it has occasionally diminished in severity for a day or two at a time it has been constant ever since. It has been severe enough at other times to retract the shoulder. The patient can control the 'twitch' voluntarily by holding the muscles of the shoulder girdle taut. When they tire the condition begins again. Moreover, as long as she is working the 'twitch' is not present. But relaxation even for the shortest time will immediately set the contraction in progress. Her main problem is sleeping. She lies in bed and is unable to sleep until the contractions stop and she states that she is frequently awakened by them. There is no history of trauma. Physical examination is negative and there are no significant observations in blood count, urine analysis or Wassermann reaction. She has been taking one-fourth grain (0.016 Gm.) of phenobarbital four times a day which has not helped the situation much. These details are about all I can give. Please let me have your suggestions as to diagnosis and therapy. Kindly omit name. M.D., New York.

ANSWER—While this would be looked on as a case of functional "tic" analogous to spasmodic torticollis by those who consider the latter a "tic," it is more likely that the condition is disease of the lenticular nucleus or other part of the extrapyramidal motor system. Such disease might be primary "dystonia lenticularis" (dystonia musculorum progressiva), a sequel of unrecognized encephalitis, or possibly even early paralysis agitans. If phenobarbital has proved ineffective, scopolamine should be tried.

LOCAL ANESTHESIA FOR SURGERY ON PERI-
TONSILLAR ABSCESS

To the Editor—Will you please tell me the most satisfactory method of using local anesthesia for opening a peritonsillar abscess?

PAUL J. FLORY, M.D. Pawnee City, Neb.

ANSWER—There is no really satisfactory method of anesthetizing the palate locally in order to open a peritonsillar abscess. There are a number of methods in use, all of them offering satisfactory results at times, but all of them have their defects. One can paint a fine streak with from 30 to 70 per cent phenol, making sure that the applicator is not dripping, in the line of the expected incision. Phenol, however, used in

this fashion may cause a little local necrosis. One may inject a solution of procaine and epinephrine. The objection to this is that it is surgically unsound to inject solutions into infected areas. Finally one may use a curved cotton tipped applicator dipped in 10 per cent cocaine and passed along the floor of the nose backward until it rests on the nasopharyngeal aspect of the soft palate. Here the cocaine will rest on the nerves that go to supply the region involved and produce frequently enough a satisfactory anesthesia.

PLASTIC SURGERY OF NOSE

To the Editor—Is it possible to pare down an anteriorly bowed nasal bone by approaching the operation from within the nasal cavity? The condition is a congenital one. If this is possible what are the chances of dimpling of the skin at the back ridge of the nose as a complication? The patient a girl has a nose that appears in profile with an abnormal forward bowing of the ridge. Please omit name. M D Wisconsin

ANSWER—Convexity of the nasal bridge is usually congenital and may involve the bony or cartilaginous portion or both. The correction of this deformity is accomplished by an intranasal operation that leaves no visible scar or dimpling of the skin. The projecting portions of bone and cartilage are removed after the skin has been lifted and the profile is reduced to the desired level. It is usually necessary also in these cases to elevate the tip of the nose slightly in order to forestall the apparent lengthening that would result from merely removing the hump. It usually takes from ten days to two weeks for the postoperative swelling to disappear and the operation in no way impairs subsequent strength of the supporting structures.

FORMIC ACID BURNS OF HANDS

To the Editor—I have a case of formic acid burns of both hands. Everything I know of has been tried to heal them. New blebs form after each dressing. These break down and form new ulcers. Have you any treatment to suggest? Please omit name. M D Massachusetts

ANSWER—Formic acid may burn and blister the skin with the subsequent development of keloids in some of the cases. When these burns occur, immediate free irrigation of the affected sites with a weak aqueous solution of sodium bicarbonate should be applied until all the acid is neutralized and the pain relieved. The areas may then be painted with a 3 per cent aqueous solution of gentian violet. If new blebs continue to form, it is well to continue frequent irrigation. The use of bland ointments is also of value to promote healing in some of these cases.

INFECTIOUS ADENITIS

To the Editor—In THE JOURNAL, May 30 under Queries and Minor Notes there is a question headed Infectious Adenitis or Mononucleosis signed M D Georgia. I would point out that the reply is incomplete to say the least. The questioner has given a carefully detailed history which in itself would strongly suggest undulant fever. Adenitis is not a rare finding to brucellosis. All the laboratory data given would fit into the well established picture of undulant fever. The gradually rising white blood count with increase of lymphocytes at the expense of polymorphonuclear leukocytes is commonly seen in brucellosis. All other tests were negative. Agglutination occurred with Brucella abortus in a 1:20 dilution of the blood serum late in the course of the illness—a usual finding to brucellosis. (This could be a cross agglutination of no significance.) Angle Evans and others including myself have repeatedly pointed out that agglutination with Brucella abortus in a low dilution of blood serum is just as significant as agglutination in higher dilutions in patients exhibiting a clinical picture of undulant fever. Finally in the May 12, 1935 issue of THE JOURNAL under Queries and Minor Notes there is a question framed as follows: "In making a diagnosis of undulant fever in patients who show the clinical symptoms suggesting the disease I should like to know how high the titer must be in the serologic test before the diagnosis can be safely made. In reply the following remarks appeared among others: Diagnostic significance is usually attributed to agglutination in dilutions of 1:80 or above. It cannot be said however that there is any arbitrary diagnostic agglutination titer. While the serums of most individuals who exhibit a more or less well defined clinical picture of undulant fever will show agglutination in titers of 1:80 or above occasional cases will be encountered in which no agglutinins are present or agglutinins will exist in titers of from 1:10 to 1:40. Ordinarily serum agglutinins do not appear until a week or ten days after the onset of illness. In some cases however agglutinins may not appear for several weeks."

In your reply should not undulant fever have been suggested at least as a possible diagnosis? In addition to the suggestion that an agglutination test with sheep's red cells be done a blood culture for Brucella abortus might also have been suggested as well as further agglutination tests with Brucella abortus to detect a possible rising titer.

Book Notices

Disease and Destiny By Ralph H Major M.D. Preface by Logan Clendinning M.D. Cloth Price \$3.50 Pp 338 with 47 illustrations New York & London D Appleton Century Company Inc. 1936

Dr Major's thesis is that disease whether affecting a single individual or great numbers of men may have a profound influence on subsequent events. The diphtheria that strangled George Washington, the smallpox that caused the death of Louis XV, the syphilis that wrecked the brain of Nietzsche had results as definite as had the bullet that took the life of Abraham Lincoln or the daggers that ended the career of Julius Caesar. The mass destruction of peoples by plague, malaria, yellow fever changed the history of cities or even of nations, at times the effects were world wide in extent. The diseases discussed by the author are familial hemophilia and nine parasitic diseases—plague, typhus, tuberculosis, smallpox, diphtheria, malaria, leprosy, yellow fever and syphilis. Dr Major knows his subject. He is a practitioner, teacher, investigator, and an ardent student of the history of medicine. He is not satisfied to be a compiler at second hand, he goes to original sources. His wanderlust has impelled him to travel in the Old World, as in the New, not alone the familiar routes of the tourist. His joy is to turn aside to visit less known places, to explore the narrow street, to enter the house or the very room where some celebrity lived or died, to seek out in the library some faded manuscript or rare first edition, or to study or photograph some forgotten but significant painting. It is the result of these excursions into by-paths that gives to the book the feature of human interest that always makes such a strong appeal to readers. The author has not intended to write an encyclopedic work far otherwise. The stories of malaria and yellow fever, for example, are by no means complete. But they convey much of information and attract one by their thumbnail sketches of Laveran, Ronald Ross, Finlay, Walter Reed, Gorgas. These men stand out as living personalities and not as conventional contributors of dry facts. Possibly one might criticize the writer for at times letting his enthusiasm lead him to describe individuals or their topical setting in such detail as to get him rather far away from his main theme, i.e., disease and its influence on destiny. That Ross was a poet and a mathematician

of note has a remote bearing on the question of malaria. Yet we are glad Dr Major wrote as he did, rather informally or even discursively, for it makes the reading of his pages a refreshing pleasure. All physicians, whether general practitioners or specialists, even well informed medical historians, will enjoy the book. The layman should find it attractive and illuminating. The author clearly had them in mind as he wrote and with a higher purpose than merely to please. There is not one of the chapters that does not convey an implied or frankly expressed lesson—the value of research in laboratory and at the bedside, the necessity for vivisection and of necropsy if scientific medical progress is to be made, the importance of preventive medicine and of public health activities, the nature of rational treatment of disease. Cults, pure empiricism, blind adherence to dogmatism and tradition find little comfort here. Altogether one must put on the book the stamp of emphatic approval. It deserves the success that was accorded Dr Major's earlier volume "Classical Descriptions of Disease."

Les voies aériennes et la tuberculose Par Georges Portmann professeur de clinique oto-rhino-laryngologique à la Faculté de médecine de l'Université de Bordeaux et Henri Retrouvey. Bibliothèque de phthisiologie sous la direction de Léon Bernard. Paper Price 50 francs Pp 312 with 30 illustrations Paris Masson & Cie 1936

This excellent book is one of a monograph series on tuberculosis, the Bibliothèque de phthisiologie, edited by the late Leon Bernard. According to the authors the purpose of this monograph is to relate and discuss the clinical aspects, the problems and the diagnosis of tuberculous lesions of the upper air passages, in connection with their relations with pulmonary tuberculosis. Chapters are added on nontuberculous infections of the nasal sinuses, nasal deformities that have a bearing on respiration, foreign bodies in the air passages, and hemoptysis that can originate in nontuberculous conditions in the upper respiratory tract. Four excellent roentgenograms of the accessory sinuses are reproduced and the associated conditions of sinusitis and bronchitis, which gave so much difficulty in the differential diagnosis of pulmonary tuberculosis during the World War, are well described. All forms of tuberculous lesions of the nose, pharynx, trachea and larynx are carefully described. Pictures portraying tuberculous laryngitis from the earliest myopathic form to the late perichondritis are admirable. The pathology of the tuberculous lesions is discussed and the lymphatic and hematogenous routes of these complications of pulmonary tuberculosis are carefully criticized, as well as direct infection from sputum. The distribution of the cervical lymph nodes is given a full page illustration. Climatic treatment, rest treatment and the effect of pulmonary collapse therapy on the upper respiratory tuberculous lesions are all matters thoroughly presented. A case is related of Vernieuwe's in which alcohol injection into the recurrent laryngeal nerve of the left side for serious ulceration with edema produced a paralysis of the cord for three months and resulted in cure. The case is referred to as one of "collapsothérapie hémilaryngée." One is surprised to find under general therapy that gold and rare earth salts have been found of benefit in certain upper respiratory lesions. Emil Bogen in a comprehensive study of the effects of all elements on tuberculosis found no favorable effect from cerium and most unfavorable results from beryllium in his work on guinea-pigs. In clinics for tuberculosis in this country, more and more emphasis is being placed on the use of the bronchoscope in patients when collapse therapy has not succeeded in making the sputum negative or when hemoptysis persists in spite of collapse therapy. Not only have tuberculous lesions in the trachea been found in such patients, but also ulcers in the bronchi which have yielded to local treatment. These matters will probably be given more stress in subsequent editions. It is a charming characteristic of the French to honor distinguished physicians. In this well written work one finds such terminology as "the disease of Brindel," "the malignant tuberculous pharyngitis of Letulle," "the acute military tuberculous pharynx of Isambert," "the subacute military tuberculous pharynx of Escat" and "le bacille de Koch" for the tubercle bacillus. The bibliography contains about 250 references and is compiled from the actual publications to which the authors had access.

Emergency Surgery By Hamilton Bailey FRCS Surgeon Royal Northern Hospital London Second edition Fabrikoid Price \$14 Pp 842 with 812 illustrations Baltimore William Wood & Company 1936

This work has been thoroughly revised and rewritten. The introductory chapters are on intravenous infusion, blood transfusion and anesthesia. Emphasis is placed on the necessity for the surgeon to be trained to meet any emergency. The treatment of general peritonitis is taken up from the point of first determining the cause. Cecostomy has proved of value. Operation for acute perforated appendicitis is not usually attempted after fifty hours except when there is general peritonitis, in children, after a cathartic and when one is in doubt as to the diagnosis. Urgent operations for various conditions in the abdomen, including the viscera and the intestine, are taken up first as to the diagnosis and then as to the proper treatment. The technic of operations for hernia and on the female pelvis are included. A comprehensive survey is given of the genitourinary organs. Emergency conditions are discussed rather briefly as they affect the thorax, spine head face, neck, bones, joints and extremities. A good section is that on hand infections. Acute infections and burns are included. Chapters on the eye and ear are written by collaborators, the field of general surgery being the work of the author. The clear and practical advice given over such a large field conclusively demonstrates an extensive experience. It is with pleasure that one reads the methods and particularly the indications for operation by a master surgeon. To the younger man in search of well seasoned advice the volume should prove invaluable.

Exploration radiologique des colons et de l'appendice au moyen des solutions flocculantes. Images de muqueuses. Technique sémiologie syndromes. Par Georges Malngot électro radiologiste de l'Hôpital Laënnec Raymond Sarasin et Henri Duclos assistant de radiologie à l'Hôpital Laënnec. Travail du service de radiologie de l'Hôpital Laënnec. Préface de Antoine Béchère membre de l'Académie de médecine. Cloth Price 200 francs Pp 229 with 203 illustrations Paris Mosson & Cie 1935

According to the preface, this is the composite work of three roentgenologists, who were not given special introduction because of their apparent eminence in France. The book describes a method of examining the colon and appendix by means of a colloidal solution of thorium oxide. Essentially the technic consists of an injection of the opaque medium and the examination of the colon first under pressure, secondly after elimination and thirdly after the injection of air. The modus operandi is attributed to the precipitation of the colloidal material on the mucosa of the bowel. In the first part of the procedure one develops the usual routine picture, in the second part the bowel appears as a network of interlacing lines that are attributed to the folds of the mucosa outlined by the precipitated thorium, and in the third part the distended bowel takes on a spotted appearance as the result of the separation of the precipitated thorium. Any departure from the normal is thus demonstrated particularly in the second and third parts of the routine. Disturbances in the intricate pattern of the mucosal relief are easily seen and in the third portion the pathologic lesions become outlined because they interrupt the snowstorm pattern. The book is excellently printed and a great number of illustrations some of which appear to be retouched, are shown describing the various pathologic lesions. This combined effort is a worthy contribution to a field that is already well filled. The method of presentation is clear and easily read.

Basal Metabolism in Health and Disease. By Eugene F. Du Bois M.D. Medical Director Rusell Sage Institute of Pathology New York Third edition Cloth Price \$5 Pp 494 with 98 illustrations Philadelphia Lea & Febiger 1936

In this edition Professor Du Bois's book has been almost entirely rewritten and much new material added. It is a remarkable book in that all the valuable literature on the subject both scientific and clinical is presented together with the extensive calorimetric investigation carried out under his direction in the Rusell Sage Institute of Pathology in an interesting and exhaustive manner. Du Bois has succeeded in his aim to bring basal metabolism out of the realm of pure physiology into the domain of clinical medicine and in doing this has made the book of the greatest value to the clinician and general practitioner. The work is indispensable to all research workers

in the field of metabolism. The book, as before, is divided into two parts. Part I, on metabolism in health, is enriched by a more ample discussion of the mechanism of the loss of heat from the body in which for the first time the subject of radiation is accurately presented in an understandable manner. This chapter will be of particular value to modern heating and ventilating engineers, as it opens up the possibility of developing new methods of heating rooms. The chapters on the biologic significance of the surface area and on normal standards have been clarified and enlarged by full discussion of the recent publications on these subjects including the studies of Boothby, Berkson and Dunn, which have not yet been printed. Part II, on metabolism in disease, has been enriched by a careful review and discussion of the vast literature on the subject that has appeared in recent years. It is this part which renders the book indispensable to the clinician and general practitioner.

The Specificity of Serological Reactions By Karl Landsteiner M.D. The Rockefeller Institute for Medical Research New York Cloth Price \$4 Pp 178 Springfield Illinois & Baltimore Charles C Thomas 1936

The review (THE JOURNAL, March 24, 1934, p 958) of the original edition in German (Landsteiner, Karl Die Spezifität der serologischen Reaktionen, Berlin, Julius Springer, 1933) is repeated here because it describes clearly the purpose and character of the book. "The purpose of this monograph is to summarize the results of the work of the author and his co-workers on antigens and to discuss serologic specificity and related questions. As would be expected from the leader in the chemical study of specificity, attention centers mainly on chemical work bearing on fundamental problems. The presentation follows essentially the development of this work. There is an introductory statement of the concept of specificity, which is followed by sections on the serologic specificity of proteins, on the specificity of cellular antigens, on the specificity of the antibodies, on serologic reactions with artificial antigenic complexes and simple chemical substances, and on chemical investigations of specific cell substances (carbohydrates, lipoids). The author is a master of clear, concise, correct statement. His method of reviewing published work is a model of exactness and concrete precision. Not a word is wasted. Landsteiner's monograph is a classical contribution. It should be translated into English. The present edition in English follows the plan of the German original, only such changes have been made as were necessary to incorporate into the text the significant new facts that have come to light in the meantime. No elaboration of the earlier review need be attempted, but it may be permitted to say that the book is of exceptional merit and deserves fully the praise bestowed on its predecessor.

Elektrokardiographische Befunde bei Herzinfarkt. Von Anton Jerrell. 1. Assistent Acta Medica Scandinavica Supplementum LXXVII Paper Pp 267 with 74 illustrations Oslo Kistenes Boktrykkeri 1935

This well written monograph, in German, is a detailed presentation of the electrocardiographic observations in sixty six clinically diagnosed cases of myocardial infarction in sixty five unselected patients, observed from 1931 to 1935. Serial curves, frequently numerous, were recorded in fifty seven instances. There are additional serial records of other conditions showing graphic alterations that simulate infarction. These, with diagrams of infarct localization as determined by necropsy, furnish an abundance of illustrations. A protocol of each case is included. There were forty-five men and twenty women in the series. ST interval displacement, a frequent early observation persisted longest in the precordial lead. Progressive T wave changes were of T₁ type in thirty five and of T₂ type in twenty-one instances. ST interval and T wave alteration, the most dependable diagnostic graphic change, occurred in forty-nine cases. The precordial lead revealed characteristic changes in twenty-six of the thirty-six instances in which it was employed. Extrasystoles occurred in thirty four supra ventricular in nine, ventricular in twenty-three, both forms in two auricular fibrillation or flutter in seven, paroxysmal auricular tachycardia in one, auriculoventricular dissociation in three, prolonged auriculoventricular conduction in three, sino-auricular block in one, sinus bradycardia with interference dissociation in one, bundle branch block in seven, of the com-

mon type in six, of the uncommon type in one, arborization block in five, low voltage in fourteen, deep Q_2 in nineteen and deep Q_3 in five cases. Of these electrocardiographic changes, arborization block alone appeared to be of prognostic significance. Necropsy was performed in twenty-six instances. Of sixteen with anterior infarction, eleven presented curves of T_1 type and three showed arborization block, whereas in two the graphic changes were of indeterminate type. Of the remaining ten with posterior infarction, all showed graphic changes of T_2 type. The material is unusually well presented. The pertinent literature is discussed in a clear and logical manner. A carefully selected bibliography includes reports of all the significant work on the subject and gives full recognition to American contributions. The monograph is a valuable addition to our knowledge of myocardial infarction, of particular interest to the clinician.

Die Entstehungsursachen der Haffkrankheit in dem Zeitraum von 1924 1933 vom epidemiologischen Standpunkt. Von Dr. med. Friedrich Wolter. Leiter des Hamburgischen Forschungsinstituts für Epidemiologie. Auf Grund des von der Regierung in Königsberg 1. Pr. zur Verfügung gestellten amtlichen Materials dargestellt. Kleine Hippokrates Bücherei Band VII. Herausgegeben von Prof. Dr. med. Kurt Klare Scheidegg. Boards. Price 4 50 marks. Pp 50. Stuttgart & Leipzig: Hippokrates Verlag GMBH 1936.

Several "new diseases" have come into the circle of medical interest during the course of the last two decades, among them German investigators have studied a curious epidemic on the Baltic coast near Königsberg. The syndrome of this 'Haffkrankheit' includes the sudden onset of muscle pain and spasm, involving chiefly the muscles of the trunk, together with rather characteristic urinary changes, including hematuria and albuminuria. The clinical course is one of repeated attacks, with ultimate progression to chronicity and involving finally severe degenerative changes in the kidney, the musculature and the heart, together with profound metabolic disturbances. The Germans have used the term "Haff disease" because of its regional appearance in the lower stretches of the small rivers leading to the sea in the region of Königsberg. Wolter, who is the director of the Hamburg Institute of Epidemiology, discusses the various etiologic possibilities and stresses particularly the meteorological conditions and the general relation of the appearance of this disease to the climatic cycles. He points out the similarity of the clinical picture to the "Bornholm disease" of Madsen. While of general interest to the epidemiologist, the monograph offers little that is concrete, and relatively much in the way of generalities.

Time of Ovulation in Women. A Study on the Fertile Period in the Menstrual Cycle. By Carl G. Hartman. Department of Embryology, Carnegie Institution of Washington. Medical Aspects of Human Fertility Series. Issued by the National Committee on Maternal Health, Inc. Cloth. Price \$3. Pp 228 with 72 illustrations. Baltimore: Williams & Wilkins Company 1936.

This little book, published under the auspices of the National Committee on Maternal Health, is a calm, concise and critical review of our knowledge concerning reproductive phenomena, especially as this bears on the correctness or incorrectness of the much discussed doctrine of a "safe period" of the cycle. Written as it is by a biologist whose life work has been in this field, its tone is in refreshing contrast to at least a good many of the scientific, lay and religious publications on this subject which have appeared in such profusion in the past few years. The author presents an excellent outline of reproductive physiology, paying especial attention to the question of the time of ovulation, a problem to which he himself has made important contributions. With reference to the Ogino-Knaus theory he concludes that "as the more objective and reliable proofs accumulate they show a trend decidedly toward a complete denial of ovulation in the last quarter of the cycle, i. e., toward the establishment of the Ogino-Knaus law. But thus far we cannot yet give this a final approval." The chief reason for this is the general unreliability of the available human data largely because of the paucity of really accurate menstrual records. The format and typography are excellent and the style of writing simple and clear, so that, in spite of the complexity of some of the problems discussed the book should be of value not only to the medical reader but also to the more intelligent and biologic minded laywoman seeking information on this subject. A foreword has been contributed by Dr. R. L. Dickinson.

Hydrotherapy and Climatotherapy. By Matthew B. Ray, D.S.O., M.D., M.R.C.P., Senior Physician, The British Red Cross Clinic for Rheumatism, Polo Place, W. J. London. With a foreword by The Right Hon. The Lord Horder, K.C.V.O., M.D., F.R.C.P., Cloth. Price 12s. 6d. Pp 312. London: Edward Arnold & Co. 1936.

The author has collected data concerning most of the important health resorts in the British Isles and Europe and some in Africa and Asia and presents in a clear and concise manner the hydrotherapeutic and climatological value attributed to each. A short discussion is given of the method of procedure at each resort, and the various diseases in which baths and favorable climatic conditions have proved helpful are mentioned. The subject matter is presented in an interesting and orderly manner so that the practitioner may readily determine which health resort is best suited to his patient's needs. The volume contains much new and useful information concerning the manner in which human physiologic function is influenced by the various hydrotherapeutic procedures in use today as well as the relationship of barometric and climatic conditions to health and disease. In Europe, where the population as well as the medical profession is definitely spa minded, this book should fill a distinct need. In this country the interest in our watering places and health resorts, at least as far as the medical profession is concerned, is of comparatively recent inception. A committee to investigate American spas has recently been appointed by the American Society for the Study and Control of the Rheumatic Diseases and it is to be hoped that Dr. Ray's book may serve as a pattern for a similar work on the spas of this country.

Synopsis of Clinical Laboratory Methods. By W. E. Bray, B.A., M.D., Professor of Clinical Pathology, University of Virginia. Cloth. Price \$3.75. Pp 324 with 43 illustrations. St. Louis: C. V. Mosby Company 1936.

In the words of the author as stated in the preface, "the object of this synopsis is to bring together in a small volume for ready reference the more recent information and the most frequently used methods of laboratory diagnosis." Dr. Bray has accomplished his purpose excellently. The book begins with a list of the various services and special cases and the tests and routines applied to each. Then follow well organized, well illustrated chapters on every division of laboratory work: urinalysis, blood chemistry, bacteriology and surgical pathology. Each begins with a brief discussion of general rules and procedures that apply to the subject under consideration. Next are the routine and special procedures. Each is given specifically, only reliable new methods and most of the more favored methods are included. The author states, when necessary, which methods are preferable for determining certain facts, and gives the relative reliability and significance of the procedures. The volume concludes with a list of indicators, stains, staining solutions, reagents, and the preparation of each, removal of laboratory stains, atomic weights, a table of equivalents and a table of normals. This brief but complete volume will be appreciated by laboratory technicians and physicians.

The Married Woman. A Practical Guide to Happy Marriage. By Gladys H. Groves and Robert A. Ross, M.D., F.A.C.S., Cloth. Price \$2.50. Pp 278. New York: Greenberg 1936.

Even in a span of ten years one can see a change in the books on marriage. Gone the moralistic, solemn sermon about the holiness of marriage. There is no more emphasis on the spiritual love and there is more talk about the real practical issues involved. This book deals with problems of marriage frankly and openly, with a good deal of emphasis on the intimate relationships of marriage. The question of sex in marriage is taken up in detail and the authors are not afraid to tackle some of the problems involved in the sex adjustment of the newly married couple. If anything the book overemphasizes the physical relationships in marriage and in that sense it carries a definite message and a plea. One may wish for a more extensive discussion of the later years of married life and problems involved in the raising of children, which, of course, can easily take up another volume. On the whole the book is practical, intelligent and frank and can be safely recommended to young married people. The placing of the responsibility for sex adjustment on the woman is a rather new note in books of this type, being obviously a welcome change.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Embalmers State Board of Embalmers Liable for Unauthorized Acts—The plaintiff a licensed embalmer, was employed as manager and embalmer of the Oregon City Funeral Home. This concern applied to the state board of embalmers for a license to conduct its business. The board as a condition precedent to the issuance of the license required the funeral home to discharge the plaintiff and to agree not to reemploy him. The plaintiff sued the board for wrongful interference with his employment, and from a judgment in favor of the plaintiff the board appealed to the Supreme Court of Oregon.

The board contended, among other things, that it was a quasi-judicial body and as such was not civilly liable for acts done within the scope of the board's lawful jurisdiction. In passing on the application of the funeral home for a license, the board contended, it was acting within the scope of its authority. But, said the Supreme Court of Oregon, the board was authorized to issue, renew, suspend, revoke and refuse to issue or renew funeral directors' licenses. It was not authorized to require any applicant for a license to discharge an employee and to agree not to reemploy him. In making such a demand the board was without any jurisdiction. In doing so it did not merely exercise jurisdiction erroneously; it acted without any jurisdiction. In proposing to withhold the funeral director's license unless the plaintiff was permanently discharged, the board did not exercise any legal right. Having thus acted without any jurisdiction, the board, the court said, may be held civilly liable for injuries sustained by the plaintiff. The judgment for the plaintiff was consequently affirmed.—*De Marais v Stricker (Ore)*, 53 P (2d) 715.

Health Insurance Postoperative Hernia and Inability to Follow a Gainful Occupation—The defendant insurance company promised to pay certain benefits to the plaintiff if he became so disabled as to preclude him from following a gainful occupation. The plaintiff, who had always been a farmer and knew no other calling, owned a large plantation on which resided sharecroppers. In operating his farm he did considerable manual work, rode a horse, drove an automobile, operated a tractor, and actively supervised the work of his tenants. He underwent an operation for the removal of a ruptured appendix. About four months later, a large postoperative hernia developed. The insurance company paid benefits for more than a year and then stopped payments. The plaintiff then sued the company, and from an adverse judgment the insurance company appealed to the Supreme Court of Louisiana.

There was no conflict in the evidence concerning the inability of the plaintiff to perform strenuous labor, but the company contended and produced testimony in support of the contention that the plaintiff, with the aid of an abdominal support, could attend to his normal duties in connection with superintending the operation of the farm. On behalf of the plaintiff, however, witnesses testified that he was unable to ride a horse, drive an automobile or walk any considerable distance, and that any physical exertion might enlarge the hernia and cause strangulation of the intestine. The plaintiff himself testified that such activity as he had been able to engage in resulted in exhaustion, extreme nervousness, nausea, headaches, and gallbladder disturbances.

The general rule said the Supreme Court is thus stated in 14 Ruling Case Law 1315:

total disability contemplated by an accident insurance policy does not mean a state of absolute helplessness which can result only from loss of reason. On the contrary, total disability is inability to do substantially all the material acts necessary to the prosecution of the insured's business or occupation in substantially his customary and usual manner.

In the opinion of the court the evidence was overwhelming that the plaintiff was totally and permanently disabled from operating his farm in the same manner in which he did before

the appendectomy, and the court could not bring itself in disagreement with the finding of the trial court that the plaintiff was incapable of riding a horse or driving an automobile for the length of time required of a superintendent of a farm to perform his duties without discomfort, pain, and danger to his health and life. Furthermore, the court said, the refusal of the plaintiff to submit to an operation to relieve the hernia did not justify the insurance company in refusing to pay him the benefits. The suggested operation, the court said, would not only be dangerous to the plaintiff's life, but also there was no definite assurance that the hernia would not recur. In the opinion of the court, the plaintiff should not be compelled to submit to an operation or else forfeit his right to disability instalments, because it was obvious that such an operation would seriously endanger his life. The judgment of the trial court for the plaintiff was therefore affirmed.—*Boughton v Mutual Life Ins Co of New York (La)*, 165 So 140.

Workmen's Compensation Acts—Epilepsy Attributed to Trauma—The worker, a young man who, according to the evidence, had always been well and strong, fell and struck his head against an iron radiator. He was unconscious for some hours. About a month later he developed symptoms of epilepsy and grew progressively worse. Attributing the epilepsy to the fall, he instituted proceedings under the workmen's compensation act of Tennessee and the trial court rendered judgment in his favor. The employer then appealed to the Supreme Court of Tennessee.

The employer contended that the epilepsy caused rather than resulted from the fall. The evidence, said the Supreme Court, did not sustain this contention. The employee testified that he fell when the chair in which he was sitting in a leaning position slipped from under him. There was evidence that he had never before had any head injury or shown any symptoms of epilepsy. Expert witnesses testified that the epilepsy may have resulted from the fall and the incidental brain injury. When, said the Supreme Court, a well man, with no history suggestive of brain disease, suffers a severe head injury and later develops brain trouble, without other or intervening apparent cause, the lay mind reasonably connects the affliction with the injury, and, when medical experts testify that such result may follow from such an injury, the causal chain is essentially complete. The judgment in favor of the worker was affirmed.—*Sears-Roebuck & Co v Finney (Tenn)*, 89 S W (2d) 749.

Optometry Corporate Practice of Optometry Illegal in New Jersey—The supreme court of New Jersey, in denying a writ of mandamus to compel the secretary of state to file the petitioners' certificate of incorporation to "engage in the practice of optometry, through duly registered licensed optometrists in its employ," held that a corporation is incapable of practicing optometry in New Jersey. Statutory provisions in this state, said the court, provide for the issuance of a license to practice optometry only to those who have met certain qualifications, and corporations cannot possess those qualifications. The legislature never intended, said the court, the creation of a corporation to do that which the law permits the individual alone to do.—*Teschel v Mathis, Secretary of State (N J)*, 183 A 146.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Bone Marrow and Lymph Node Changes in Experimental Radium Poisoning—Rosenthal and Grace reproduced in rabbits by the oral administration of radium sulfate the general features of radium poisoning as observed in human cases. Jaw necrosis, a characteristic of the early acute cases among radium dial painters can be produced experimentally by radium alone without mesothorium. Striking changes are produced in the bone marrow, consisting of an early hyperplasia of the erythropoietic elements followed by a decreased maturation of the erythroblasts and the replacement of these elements by myelocytes. Finally this hyperplastic marrow is replaced by fibrous tissue. In the lymph nodes there is noted an initial stimulation of the stem cells with subsequent damage to these cells resulting in depletion and atrophy of the lymphoid tissue. In the circulating blood an absolute lymphopenia is found. The development of myeloid tissue in lymph nodes and spleen associated with the extreme myelocytic hyperplasia in the marrow of the animals suggests that the occurrence of leukemia in x-ray and radium workers may not be a pure coincidence.

Systolic Blood Pressure in Renal Tumor—Morlock and Horton studied the alterations of the blood pressures of 491 persons having renal tumors. In 459 cases there was a record of the preoperative systolic blood pressure, in 335 of which a pathologic diagnosis of renal adenocarcinoma of the hypernephroma type was made, 247 of the patients were males and eighty-eight females. Of this group of males 60 per cent had a normal blood pressure between 100 and 139 mm of mercury, 0.8 per cent had definite hypotension, that is, a systolic pressure less than 100 and 39.2 per cent had hypertension that is a systolic pressure of 140 or more. When the actual readings of blood pressure were plotted and the arithmetical mean of the different age groups was superimposed in the form of a curve it was found that this closely approached the curve

obtained by a similar analysis of a large series of normal males, being perhaps slightly but hardly significantly elevated above the normal value. The blood pressure, taken from a few days to several years postoperatively was recorded for eighty-one of the males who had hypernephroma. The mean values of these readings closely approximated the mean for normal males. In the eighty-eight females with hypernephromas the mean value was found to approximate closely that obtained by a similar analysis of normal females, although it is consistently slightly higher. The postoperative blood pressure was recorded in seventeen of these cases. Eight of the patients had a postoperative reading between 100 and 139 and nine had a reading of 140 or more. That the incidence for the different ranges of blood pressure was practically unaltered by removal of the tumor seems to the authors to be significant. The mean preoperative systolic blood pressure for the males with hypernephroma was 136 for the females 145. Though these values are admittedly elevated over those considered normal, if it is considered that this is due to the pressor action of a substance secreted by the hypernephroma there is no explanation why removal of the tumor does not consistently result in a lowering of the blood pressure. That such a drop does not occur is evident, in that the mean postoperative value for the blood pressure of males and females who had hypernephroma is 133 and 144, respectively. There were seventy-six males with renal tumors other than hypernephromas, 59.2 per cent having a systolic blood pressure between 100 and 139, and 40.8 per cent a systolic blood pressure of 140 or more. The arithmetical mean for this group closely approximated the normal. A postoperative record of the blood pressure was obtained in twenty-four cases, 66.7 per cent had a reading between 100 and 139, 8.3 per cent a reading less than 100, and 25 per cent a reading of 140 or more. There were forty-eight females with renal tumors other than hypernephromas, 45.8 per cent of these had a systolic blood pressure between 100 and 139 and 54.2 per cent of 140 or more. The arithmetical mean blood pressure also closely approaches the normal value. In twenty cases in which a postoperative record was made, 40 per cent of the patients had a blood pressure between 100 and 139 and 60 per cent of 140 or more. Of six cases of hypernephroma in which a definite involvement of the adrenals was proved, a marked hypertension was present in only two.

Vitamin C Deficiency and Tuberculosis in Guinea-Pig—Greene and his co-workers found that chronic vitamin C deficiency combined with a progressive tuberculous infection causes a significant shortening of the survival period and a significant decrease in the body weight of guinea-pigs. Chronic scurvy did not cause the development of generalized tuberculosis in animals infected with the relatively avirulent strain R1. Generalized tuberculosis develops more rapidly in chronically vitamin C deficient animals than in nonscurvitic animals infected by the subcutaneous or enteric route with strain H37 or tuberculous sputum. Guinea-pigs maintained on a partially

depleted vitamin C diet develop more lesions and ulcers in the intestinal tract than do animals on a complete diet when fed tubercle bacilli. When infected tuberculous sputum is fed, the extent and severity of the tuberculosis in the intestinal tract is greater than when pure cultures of tubercle bacilli are administered. Animals infected with tuberculosis and allowed to develop acute scurvy show no more tuberculosis than the control guinea-pigs.

Mechanics and Biology of Tuberculous Cavities—Corvillo presents clinical, experimental and pathologic data which he believes cannot leave any doubt on the paramount importance of the bronchial outlets of tuberculous cavities in the evolution and the fate of the latter. The mechanism of the changes occurring in these cavities from their formation to their closure is regulated by the physiologic functions of gas exchange and gas absorption of the lung. The cure of the disease, or rather its change from progressive and active to arrested and inactive, is based on the biologic needs of the tubercle bacillus of large amounts of oxygen for life and growth. The development of fibrosis in the diseased lung is simply caused by the anoxemia that follows atelectasis and ischemia of the diseased parenchyma.

Evaporation of Water from Superficial Burns—McClure measured rates of evaporation in thirteen cases of first and second degree burns, two cases of frost-bite, four cases of experimental burns produced by ultraviolet radiation and two cases in which tannic acid was applied to normal skin. It was found that evaporation has a negligible effect in producing dehydration after a severe burn. Even in children, evaporation alone could not be important. Increased concentration of the blood, such as was found by Underhill and others, can hardly be due ordinarily to loss of water from the body. This is confirmed by the constancy of the body weight during convalescence from burns. Hence water that leaves the blood probably remains in the body in the spaces in various tissues. Regulation of the normal distribution of fluid, then depends on vascular and other readjustments within the body. Treatment of burns with tannic acid reduces evaporation enormously

but the belief that the beneficial effects of tannic acid are due to the prevention of loss of water from the body is not supported by the data now available. Whatever water and protein are lost from circulation appear to remain largely within the body.

Shock Mechanism of Death Following Intestinal Obstruction—Moon and Morgan point out that the shock syndrome arises whenever there is a serious disparity between the volume of blood and the volume capacity of the vascular system. Such a disparity may develop from a decreased volume of blood, from an increased volume capacity of the vascular system or from combinations of these. In human patients with shock and in animals with experimentally induced shock there is visible postmortem evidence of an increased volume capacity of the vascular system. Evidence of this is seen in the edema of mucosae, in the effusions of serum into cavities lined with serous membrane and pulmonary alveoli and in the numerous capillary hemorrhages occurring in mucous and serous surfaces and in the parenchyma of organs. When capillaries are injured, by whatever means, the permeability of their walls is increased. When permeability of the capillaries is increased in extensive areas, the transudation of plasma through their walls causes edema in the tissues and increases the concentration of the blood. The dilated capillaries and venules are filled with viscid concentrated blood, and the heart is unable to maintain normal blood pressure because of insufficient return of blood from the periphery. As the circulation becomes ineffective, lack of oxygen contributes to further capillary atony, and the circulatory disturbance becomes more grave. If lowered blood volume and hemoconcentration are produced by plasmapheresis without injury to the capillaries, the animal may return to normal spontaneously or following the therapeutic administration of fluid. In shock, fluids are neither absorbed nor retained. Injection of them into the blood merely increases the edema. It appears that an essential factor by which shock develops and progresses is increased permeability of the capillaries. The hemoconcentration accompanying intestinal obstruction has been assigned to loss of fluid by vomiting. Such fluid comes from the blood, largely because of permeability of the capillaries. The combined effect of loss of blood volume by transudation and of increased volume capacity due to atony of capillaries and venules produces a circulatory insufficiency which manifests itself in the shock syndrome.

Survival of Autoplastic Parathyroid Transplant—Shambaugh and Cutler have clinically corroborated that parathyroid autografts will survive regardless of the physiologic need of the organism for parathyroid tissue. They assumed that in their patient the anatomic deficiency in parathyroid tissue at the time the graft was placed was 50 per cent. As far as can be determined, however, there was no physiologic deficiency. The patient showed no evidence of tetany at any time, and the calcium content of the blood did not fall postoperatively. In fact, there was a slight rise from the preoperative level of 11.2 to 11.5 mg. per hundred cubic centimeters ten days after operation and 11.8 mg. fourteen days after operation. A final determination seven weeks after operation showed the calcium content to be 10 mg. A coincidental observation was that the patient had Paget's disease of the bone involving the right ilium and, to a slight extent the skull. This probably does not signify a parathyroid deficiency and therefore does not alter the conclusion that the parathyroid autograft survived in the absence of an urgent specific physiologic demand.

Arthroscopic Examination of Knee Joint—In their arthroscopic examination of eighty knee joints, Burman and Maver encountered nine meriting individual report. In a case of sarcoid of the tendon sheath and joint, no cutaneous evidence of sarcoid was presented at any time. There was no splenomegaly but a roentgenogram of the lungs showed hilar adenopathy. Microscopically, the changes are not incompatible with those observed in tuberculosis, and a study of each tubercle would have invariably led to a diagnosis of tuberculosis. A case of synovitis of the knee joint was characterized by bodies resembling Hassall corpuscles in the synovia. Their third case, a multiple polypoid fibromatosis of the synovia of the knee joint, clinically resembles nonspecific synovitis of the knee with recurrent effusion. There is some resemblance to tuberculosis which condition must be considered in the differential diagnosis.

It is a true tumor of the knee. They encountered two cases of chronic nonspecific synovitis of the knee joint in young patients. The involvement is usually bilateral and is characterized by the presence of repeated effusions within the knee joint, with thickening of the synovial lining. Aspiration may diminish the effusion temporarily, but there is a marked tendency for rapid recurrence. Only the knee joint is involved, and no definite cause can be invoked. Trauma is apparently coincidental. The reaction to tuberculin is negative, and no signs of syphilis are present. The Wassermann reaction of the blood and of fluid from the joint is negative. It is always necessary to rule out a specific lesion, although the clinical behavior of the knee joints in these cases resembles that of syphilis more than that of tuberculosis. The disease process is seen to be confined to the synovia. In the sixth case, one of osteochondritis dissecans, the cartilage showed hypercellularity of the superficial layers and some localized thickening of the perichondrium. The synovia showed some villous hypertrophy and was the seat of chronic synovitis. Two cases of solitary intra-articular lipoma of the knee joint were observed. This is an uncommon tumor of the knee joint, the primary clinical importance of which lies in the fact that it acts as a mechanical block to motion, producing repeated temporary locking. It is the authors' opinion that the solitary lipoma arises in the presence of other diseases of the synovia and that it is such synovial irritation which rarely allows a synovial villus to proliferate so that a true lipoma is formed. While a history of direct trauma may be obtained, it is most likely that the trauma came about either coincidentally or as a result of the interposition of the tumor between the bony surfaces of the joint. Treatment consists in the removal of the tumor. The tumor should be transfixed by two needles just before the synovia is entered, otherwise, it may be difficult to locate it properly. The ultimate fate of the joint rests on the coincident pathologic process in the joint. The last case was one of sympathetic synovitis of the knee joint arising from an adjacent (abcess of tibia) bony focus. Without actual arthrotomy, the effusion within the knee seems to have been due to the subjacent bony focus, a sympathetic synovitis. This condition has occurred in many cases of joint-articular lesions, including fracture, infection and tumor. Yet it was imperative here to rule out an actual lesion of the knee, and this was done by arthroscopic visualization.

Total and Free Cholesterol in Blood Serum.—Sperry determined the concentration of total and free cholesterol in 126 samples of blood serum from ninety-one healthy adults.

The minimal amount of free in total cholesterol was 24.3 per cent, the maximum was 30.1 per cent and the average was 26.9 per cent, with a standard deviation of 1.4 per cent. The result leads to the conclusion that the percentage is far more constant than has been recognized by previous investigators, most of whom have reported much larger variations and a higher average. Support for this conclusion was obtained in the observation that a large proportion of samples taken post mortem from human beings who had died suddenly gave values in the same narrow range. Similar results were obtained in healthy children and in four fifths of a large series of determinations on diseased children. With few exceptions, values above 31 per cent were found only in the presence of infection or liver disease. The percentage of free in total cholesterol appears to be a physiologic constant that may be of considerable value in the study of cholesterol metabolism and in pathologic conditions.

Dietary Deficiencies and Certain Neurologic Syndromes.—From the study of eighty-two cases in which multiple neuritis was a prominent clinical entity, and in many of which there were mental symptoms, Perkins found that digestive disturbances were quite constantly present. A logical explanation for the lack of intake, failure of proper digestion or assimilation could be found in nearly every case. The varieties of clinical syndromes closely approximated those seen in beriberi, pellagra and sprue, which are accepted as being due to a lack of one of the vitamin groups. The known pathologic condition of the nervous system in these syndromes compares favorably with that seen in the accepted deficiency diseases. Finally, there was the therapeutic test of improvement when the patients were placed on a high vitamin diet. The failure to ingest the required amount of vitamins for that particular individual, or the inability to digest or assimilate the vitamins ingested, is responsible for the neurologic syndromes presented by the patients. Since the syndromes offer both clinical and pathologic fragments of deficiency diseases which are accepted as being due to different vitamins, the author believes that in many instances the lack of more than one type of vitamin is responsible for the pathologic changes. Until this subject has been more thoroughly investigated, these patients should be treated with a full diet rich in vitamins, especially B₁ and B. Since there are many diseases of the central nervous system in which the pathologic changes are degenerative instead of inflammatory, and the etiology is unknown, a more thorough investigation of the action of dietary deficiency on nerve tissue may bring to light at least one factor in the cause of the disease.

Pulmonary Mycotic Infections—Carter points out that pulmonary mycotic manifestations on the roentgenogram vary from case to case and from disease to disease but will simulate closely some manifestation of tuberculosis. On the whole, minority characteristics of tuberculosis are simulated. These are seen so much more frequently as tuberculosis that they are properly recognized as tuberculosis-like. However, they are definite mycotic predilections. With persistent failure to find the tubercle bacillus and with suggestive peculiarities of history, the chance of mycosis is sharply increased. Geographic location, occupation, associated extrapulmonary lesions, or characteristics of the roentgenogram of the chest may direct suspicion to mycosis or to a particular disease, such as blastomycosis, coccidioides or actinomycosis. The accuracy of these deductions is immaterial so long as they promote the decisive bacteriologic investigation. Characteristics adding to the likelihood of a mycosis are: outstanding mediastinal or hilar adenopathy, miliary lesions associated in the adult with adenopathy, absence or sparsity of dry air-containing cavities in advanced lesions, extra prominent pleural lesions, absence of an obviously older apical or subapical lesion from which the remainder of the involvement may have spread bronchogenically, growth of a consolidation by contiguous spread, lesions of bone or soft tissue abscess about the thorax, extension of involvement through the thoracic wall, hilar truncal and peribronchial thickenings, bronchiectatic manifestations, fine discrete miliary or nodular manifestations associated with fine peribronchial accentuation and cloudy parenchymal densities accompanying a subacute persistent respiratory attack. Only by detailed study of the original roentgenograms of known mycoses in volume can any degree of accuracy be attained in their roentgen diagnosis.

Influence of Roentgen Therapy on Basal Metabolism in Leukemia.—In spite of the overwhelming evidence of the prognostic value of basal metabolic determinations in leukemia and their application as a guide to roentgen therapy, Middleton and his associates have not found a wide clinical acceptance. Only five of the thirty-five leukemic subjects failed to show an elevation of the basal metabolic rate at the time of their study. Even this small minority might have been further reduced had the period of study in such instances been extended. One of these exceptions occurred among sixteen cases of myelocytic leukemia as contrasted with four among eighteen cases of lymphocytic leukemia. The opportunity to follow the progress of leukemic patients under roentgen therapy by means of periodic or routine basal metabolic determinations was afforded in twelve cases of myelocytic leukemia and nine cases of

lymphocytic leukemia. Careful analysis shows that there is but a rough parallelism between the basal metabolism and the leukocyte count, the percentage of immature cells and the clinical condition of the patient. Though commonly subjective and objective improvement was coexistent with the lowered basal metabolism subsequent to irradiation, this was certainly not invariable. Parallelism seems closer in the cases of the lymphocytic leukemia group. It appeared that symptomatic improvement more closely approximated the diminution in metabolic rate than did the hematologic observations, conforming to expectations based on clinical experience. Thus, though the metabolic rate bears a more than casual relationship to the patient's state of well being, it certainly is not an infallible guide. It furnishes but one of several indications as to whether or not irradiation is necessary at a certain time in a particular case. The results further emphasize the necessity for individualization of therapy, based on the complete clinical picture in association with judgment resulting from a wide experience in this type of case. The technic of treatment was similar in all cases, but naturally the dosage as well as the site of irradiation was individualized. The conventional high voltage therapy technic was used, the tube potential amounted to either 160 or 189 kilovolts (valve tube and condenser equipment), with a filter of 0.5 mm of copper + 1 mm of aluminum. The quality of radiation corresponded to a half value layer in copper = 0.75 mm and 1 mm, respectively. For the exposure of the spleen, long bones and lymph nodes the focal skin distance was 50 cm., for general body exposure, however, it was from 60 to 100 cm. The dose applied per field varies from 100 to 200 roentgens (in air) for local areas, and from 25 to 50 roentgens for general body exposure. Not more than three areas in the case of local exposures, and not more than two areas in the case of general body exposure are irradiated at one sitting. There is no doubt that, in the early stage, moderate potentials will produce good results, however, as soon as there is less response during a series of treatments than in the beginning, a change to high voltage therapy should be made. So far the authors have not employed general body exposure as a routine in all cases but have reserved it for those that did not respond to the usual methods, particularly in the later stage of the disease. Several striking remissions were seen among such cases.

Influence of Infections on Incidence of Coronary Thrombosis—Campbell attempts to prove that there is an association between infection and the great increase in coronary thrombosis, while in no way disputing the fact that atheroma is increasing. Infections of the gallbladder are those most commonly associated with this cardiac lesion. He discusses illustrative instances of coronary thrombosis associated with cholecystitis and presents cases of coronary thrombosis following attacks of influenza, phlebitis, pyogenic infections, syphilis and diabetes. The cases demonstrate the fact that concurrent or previous infections are found in many cases of coronary thrombosis. More cases could be quoted bearing out the same intimate relationship. It is difficult to prove that these infections are the determining cause of the severe cardiac lesion, but the fact that lesions such as those of the gallbladder are found makes it essential that everything possible should be done to eliminate any focal infection in the hope that cardiac failure may be averted. The difficulties in diagnosis are due to the fact that varying degrees of anginal pain can be simulated by gallstone colic or by the pain of cholecystitis. Attacks of coronary thrombosis have to be differentiated from ordinary angina, acute abdominal disorders, such as perforations, acute cholecystitis, acute pancreatitis, diabetic ketosis—often a transient glycosuria, though coronary thrombosis is found in diabetes—and lobar pneumonia, in which a wrong diagnosis is sometimes made.

Effect of Chloral Hydrate on the Heart—Alstead assessed the value of chloral hydrate in fifty-five cases, giving particular attention to the cardiac action and blood pressure. In thirty-three cases there was clinical evidence of heart disease and in the remaining twenty-two, though the heart was apparently normal, marked emphysema was found in seven and acute rheumatism and exophthalmic goiter in two. A hypnotic effect was produced by 13 Gm., the official dose. The drug in ordinary doses is entirely free from the disadvantages of tolerance and habit formation but is best avoided in the presence of gastro intestinal irritation, although this can be eliminated by sufficient dilution with water. Smarting of the eyelids and lacrimation were troublesome in about 5 per cent of the patients under observation. This occurred only after several days during which the dosage had been frequent and substantial.

Physical examination of the heart yielded no unequivocal evidence of weakening of the cardiac action by chloral hydrate. Only three cases appear to admit of some discussion on this point, but the results of further investigation of the cardiovascular system were inconsistent with cardiac damage. Clinical evidence of improvement in the action of the heart was seen in two cases. No significant changes occurred in the heart rate. About half the patients showed some fall in blood pressure. The decrease did not exceed 15 mm of mercury and, as there was no alteration in the condition of the heart, the change in blood pressure was regarded as being consistent with prolonged periods of sleep and almost continuous drowsiness. In the few cases in which the blood pressure was depressed more than 15 mm of mercury, conditions other than the administration of the hypnotic were regarded as being the main causes. Nearly a fourth of the patients were found to have an increased blood pressure after taking chloral hydrate. The results support the view that chloral hydrate is not particularly detrimental in the presence of heart disease. When the blood pressure is lowered during chloral hydrate administration, the effect is not much greater than occurs in natural sleep.

Transmission of Hemolytic Streptococci by Dust—White carried out tests on the air and the dust for the hemolytic streptococcus in twenty-seven single bed wards between the third and the sixth day after the patients were admitted. The dust of the twenty-seven wards housing patients who were discharging hemolytic streptococci was always contaminated with the organism, and in most cases the strain isolated from the dust was proved to be identical with that infecting the patient. The dust of similar wards housing patients infected with other organisms seldom yielded hemolytic streptococci, and then only very scanty growths. Spraying with 40 per cent solution of formaldehyde destroyed the hemolytic streptococcus in rooms contaminated with that organism. A case is reported in which exposure to dust carrying the hemolytic streptococcus was almost certainly responsible for an acute pharyngitis. Although no opportunity has occurred for investigating the point, it would seem unlikely in view of the experiments reported by Colebrook (1933) that a healthy throat carrier of the hemolytic streptococcus creates a zone of streptococcus-carrying particles around himself.

Tuberculous Thrombophlebitis of Lower Extremity—Altschuler states that in the cases of tuberculosis of veins described it was not a matter of a disease confined to the wall of the vein, the vein was infected by invasion from the surrounding tissues and there were always advanced tuberculous changes, with miliary infection of the viscera. In the authors two cases the organs are not demonstrably diseased. The tissue surrounding the vein was free from infection and only the intima was attacked. He cannot explain the etiology, no port of entry was discovered on the lower leg in spite of most exact interrogation of the patient. The inguinal glands were removed and examined but were not diseased. He believes that tuberculous disease of the veins of the extremities is not rare, and, if so, there is a wide field for research into its causes and its treatment.

Pyloric Decentration.—Chapuy believes that normally the pylorus should lie in a position which is constant in relation to the stomach. He believes that the pylorus lies normally always in the axis of symmetry of the antral region. Decentration exists in those instances in which the pylorus does not lie in this axis of symmetry. Even a slight deviation from the axis has the same diagnostic value as a more marked decentration. With roentgenographic examination these facts can be satisfactorily demonstrated. There are a few causes for error, notably error of interpretation, neoplasm of the lesser curvature of the stomach and prepyloric dilatation. These can usually be eliminated by proper technique. The author thinks that the value of the procedure lies in the fact that pyloric decentration in the absence of any other abnormal image is practically pathognomonic of gastric duodenal ulcer. Furthermore, he has been able to demonstrate delayed gastric emptying in all patients showing decentration. He believes that these facts point to ulcers as truly a disease of the stomach and that one is dealing with a purely functional image rather than a static picture.

Carbon Tetrachloride for Tapeworm.—Talice believes that carbon tetrachloride is by far the most effective parasiticide against *Taenia saginata*. Before using the substance, he attempts to avoid intestinal absorption by forbidding his patients fatty substances and especially alcohol during the treatment. Furthermore, the treatment is contraindicated in patients having icterus hepatic insufficiency, acute enteritis or generalized infections. Carbon tetrachloride has an indirect action on the blood calcium. To avoid accidents resulting from hypocalcemia he gives calcium chloride during the week preceding the administration of the drug. A dose of from 3 to 4 cc. is given according to the weight of the patient. Immediately after ingestion the patients are given a strong saline purgative and advised to rest in bed at least during the day of the treatment. During the day the ingestion of sweetened drinks is allowed. Recovery was recognized only when the head of the worm was identified. Of the sixty-seven adults treated in this manner, sixty-one were cured with one treatment. Four were cured with two treatments and two failed to return for a second treatment. The author concludes that, when used with proper precautions this method is superior to any other in the treatment of infestation with *Taenia saginata*.

- *Hypogastric Neurotomy and Periaortic and Peri Iliac Sympathectomy as Integral Part of Certain Abdominal Operations A Bojovitch—p 320

Hypogastric Neurotomy and Periaortic Sympathectomy.—Bojovitch discusses in detail nine cases in which he has performed a presacral resection and in some a periaortic and peri iliac sympathectomy in addition. Three cases were inoperable cancer of the cervix and six were different gynecologic diseases which necessitated radical abdominal operation. The three patients in the first group were operated on by lumbar anesthesia, after which a resection of the hypogastric plexus was performed with the intention of reaching as many filaments of the nerves as was possible. A similar lumbar anesthesia was performed in the second group and in several instances resection of the presacral nerve was supplemented by periaortic and peri iliac sympathectomy. After having per-

formed sympathectomy of the abdominal aorta and the iliac vessels, the author isolated the latter by means of the parietal peritoneum. The results of the procedure outlined were quite favorable. The postoperative pains which follow every abdominal operation were limited in most of the cases to the incision area. Diuresis was increased and micturition was performed several times in twenty four hours. Resection of the hypogastric plexus and the sympathectomy produced a favorable action on postoperative intestinal obstructions and diarrhea. Periaortic sympathectomy by means of its vasomotor and reflex action and by other means which are not yet clear has a favorable action on the surgically produced lesions. The author believes that this method of operation is to be recommended in several types of painful gynecologic conditions.

- Proteases in Fluids of Effusions N Fucci—p 332
- *Achylic Hypochromic Anemia in Course of Chronic Intestinal Amebiasis E Greppi and S Deleonardi—p 349

Total Creatinemia in Cardiac Diseases.—Messina studied the behavior of total creatinemia in patients suffering from cardiac diseases in conditions of compensation or decompensation and also the relations between creatinemia and the residual nitrogen in the blood of the same patients. He found that the average amount of creatinemia, which is 48 mg in normal persons, is 715 mg in patients suffering from cardiac diseases in compensation and 1227 mg in the same type of patients having decompensation. In each case azotemia is normal. Total hypercreatinemia in these cases is due to metabolic disturbances of the myocardium rather than to retention of creatine and creatinine in the blood due to renal insufficiency, and it is unrelated to azotemia.

Achylic Hypochromic Anemia in Intestinal Amebiasis.—Greppi and Deleonardi report a case of achylic hypochromic anemia in the course of intestinal amebiasis and lamblasis in an adult. The hematologic picture was that of achylic chlor anemia, which is characterized by true microcytosis with preponderance of globules of maximal resistance and scanty hemolysis. It was controlled by the administration of iron in large doses (8 Gm daily for fifty days) up to normalization of the crisis of the blood. The author states that the gastro-anemic syndrome was secondary to gastric achylia, which resulted from the presence of chronic gastritis in intestinal amebiasis. The latter, as well as certain parasitic infestations, inflammations and tumoral processes of the digestive tract, may produce a gastro-anemic syndrome, either of a pernicious macrocyte nature (pernicious anemia) or of a chlorotic microcytic one (true microcytosis). Both forms of anemia develop from a pathologic condition related to a deficiency of the gastric secretions and are in direct relation to the latter and in indirect relation to the former. Both forms of anemia are controllable by specific therapy (liver and iron, respectively) thus proving their autonomic pathogenesis. In the authors' case the normalization of the blood coexisted with attenuation of the parasitic infestation and the symptoms of colitis, probably resulting from the improvement of the digestive functions and general condition of the patient because of the normalization of the blood.

Pernicious Anemia Due to Trichocephalus Trichinra.—Battaglia and Arata's patient a woman aged 29, presented a clinical picture of anemia associated with digestive and nervous disorders. The condition had lasted for more than six months and the pallor and emaciation of the patient were extreme. The intense anemia was of a progressive pernicious type. The digestive disorders were characterized by uncontrollable vomit-

ing, nausea, anorexia and the passage of feces having an appearance of milk curd. Occasionally they had traces of blood. The nervous disorders appeared in crises of cervical pain, tremor of the extremities and crying. Neither syphilis nor infectious diseases were in the history of the patient. The examinations of the feces showed *Trichocephalus trichiura*. The administration of several treatments against the intestinal parasitic infestation until complete disappearance of the parasites in the feces resulted in gradual improvement of the blood and clinical picture with eventual recovery of the patient, which has lasted up to the present time, four years after discontinuation of the antiparasitic treatment.

Roentgen Image of Hydro-Aereal Levels in Mechanical Ileus Roentgenograms of Intestinal Obstruction and Occlusion H L Mazza—p 1559

Multiple Myeloma—According to Dassen and his collaborators, a roentgen examination of the skeleton is advisable in patients suffering from anemia of a pernicious type of unknown origin for detection of the possible presence of multiple myeloma. The most important roentgen signs are the lack of deformation of the bone and the presence of shadows corresponding to round clear zones in the bone. The disease may develop and evolve, aside from the production of fractures, presence of pain in the bones and other known symptoms, with splenomegaly and intense anemia of a pernicious type, emaciation, bilateral pleurisy and anasarca of rapid reproduction after removal of fluids. The blood picture is that of an intense anemia and favorably reacts to the administration of liver extracts. The treatment which is palliative, consists in care of the patient to prevent the production of fractures, controlling the pains by the administration of analgesics and morphine, if necessary, controlling the anemia, evacuating the pleural cavity and giving diuretics to reduce the anasarca. Arsenic fails to control anemia. Hepatotherapy controls splenomegaly and anemia but does not interfere with the general evolution of the disease and the more or less rapid progress of cachexia. Roentgen irradiations fail to improve the bone conditions. The expectancy for the life of the patient is from one to four years. One case is reported.

Treatment of Gonorrheal Vulvovaginitis in Virgins—Negrete and Fontán Balestra state that Mendez's treatment of vulvovaginitis in virgins consists in daily subcutaneous injections of a vaccine prepared with bacteria of the type found in the vaginal secretions and intravaginal application, every other day, of an ointment prepared with the same type of bacteria. The vaccines are prepared with one or more bacteria. The amount of ointment used is 5 cc for each application. The expulsion of the ointment from the vagina is prevented by covering the vulva with a piece of gutta-percha held in place by adhesive tape, thus forming a local "closed cavity." Washing of the involved parts is avoided. The patient is given every morning a spoonful of oil for correction of constipation. Bacterial examinations of the vaginal secretions are frequently made during the treatment. If the bacterial flora changes, the bacterial vaccine is also changed to one containing the bacteria present in the vaginal secretion. The treatment is discontinued altogether on complete disappearance of the pathogenic bacteria from the vaginal secretions, which takes place in a short time. The merit of the treatment consists in maintaining the vaginal exudates in direct contact with the local tissues because of their antiseptic and antibody forming properties and also in stimulating the organism to the formation of a large amount of antibodies and haptens by means of the bacterial vaccine and of the local application of the bacterial ointment. Satisfactory results in several cases of varying intensity and duration are reported.

Influence of Acidity of Milk on *Bacillus Coli*—Bock and Binder say that the favorable action of sour milks in dyspepsia of nurslings is undisputed and has been proved by years of experience. In order to explain this action it is necessary to investigate the bacterial conditions in dyspepsia of nurslings. Since other investigators have come to the conclusion that the growth of the bacilli of the group *lactis aerogenes* is hardly at all inhibited by an acid milieu, the authors decided to investigate to what extent the inhibition of the growth of *Bacillus coli* on the one hand and of *Bacillus lactis-aerogenes* on the other hand is dependent on the degree of acidity and what practical conclusions may be drawn from this as regards dyspepsias of nurslings. They determined the acid sensitivity of twenty one *B. coli* strains and ten *B. lactis-aerogenes* strains and found that the latter are only slightly less sensitive to acidity than the former and they think that this slight difference is of no practical importance. The *pH* values at which the growth of the investigated bacteria is greatly inhibited are near to or identical with the *pH* values of the sour milks. Thus it is proved that the sour milks are helpful in the prevention and treatment of dyspepsias of nurslings.

*Pathogenesis of Facial Erysipelas W Schultz—p 723
Family with Camptodactylia P Ritterskamp—p 724
Dangers of Physical Therapy in Practice F Lickint—p 727

Puerperal Neuritis of Traumatic Origin—Gachtgens points out that traumatic puerperal neuritis of the lower extremities plays a more important part than is generally assumed. He concedes that it is not always easy to differentiate it from disturbances that are of toxic origin, for the puerperal period seems to be characterized by a tendency to toxic neuritis or neuropathia. However, a traumatic cause may be assumed whenever the delivery was difficult, and particularly when obstetric interventions were necessary. The author describes two cases. Both women passed through an extremely difficult delivery. Moreover, the pelvic anomalies created the predisposition for lesions of the lumbosacral nerve trunks, and the obstetric operations increased the possibility of severe lesions of the nerves. The second case is practically identical with another case reported in the literature in that in both cases lesions of the peroneal and tibial nerves existed. The patients had a halting walk and were incapable of lifting the lateral portion of the foot and of abducting it, the capacity for plantar flexion was impaired and, as an indication of tibial paralysis, the movement of the toes was greatly restricted. In regard to the treatment, the author says that restitution depends on the severity of the lesion. He thinks that spontaneous cure may be expected in the majority of cases. To be sure, heat, massage and electrotherapy may accelerate the curative process. Induced by favorable reports about the efficacy of vitamin B₁₂ in cases of postdiphtheric paralysis and in various types of neuritis, the author gave daily subcutaneous injections of a vitamin B₁₂ preparation and noted considerable improvement after eight injections.

Pathogenesis of Facial Erysipelas—Schultz points out that at present it is generally believed that erysipelas is caused by the entrance of the pathogenic agent into defects of the skin or of the neighboring mucous membranes. The fact that the face is most often affected in cases of erysipelas is ascribed to the greater incidence of small injuries on the face and to the fact that aural and nasal diseases often are the point of origin of erysipelas. The author shows that a number of factors can be cited against this theory of pathogenesis, which is based on bacteriologic aspects. The author cites a statistical

report of 211 cases of facial erysipelas which indicates a greater incidence of the disorder in women and also in certain age groups. After puberty there is a great increase and in women the greatest incidence occurs during the menopausal age. This fact indicates that facial injuries cannot be the chief factor, for injuries of the face or of neighboring organs are not more frequent in that age group. Further, the author calls attention to a relationship with tonsillar infections. In this connection he cites the case of a woman aged 46, who developed a facial erysipelas after nursing children who had tonsillitis and he assumes that the facial erysipelas, like the tonsillitis, developed hematogenically. At any rate there is considerable evidence that in many cases of erysipelas constitutional factors play a part and that there is some justification for the hipocratic differentiation between idiopathic and traumatic erysipelas.

Atypical Lead Poisoning by Tap Water—Altmann and Nowotny describe four cases of a complicated but primarily spinoperipheral neurologic disorder, which were observed at their clinic within a comparatively short period. The diagnosis as well as the etiology presented at first considerable difficulties, but the fact that the four patients came from the same district of a city in Lower Austria led to the discovery that the lead content of the tap water of that district was responsible for the disorders. The urine of the patients showed a considerably increased porphyrin content and also lead, and the drinking water of the city in question contained much more than the permissible amount of lead. However, although more than 5,000 persons were exposed to the same influence, the four persons (three were women) whose cases are described here were the only ones who contracted this disorder. The authors think that this indicates a predisposition for lead poisoning, which has been observed also among workers who are exposed to lead intoxication.

Hypoglycemia in Apparently Healthy Persons—Janssen states that although the symptoms of hypoglycemia are well known nowadays to every practitioner and the patient himself generally notices the initial disturbances it is surprising that children do not notice them and consequently are unable to give timely warning of an impending attack. Hypoglycemia in children often is ushered in by changes of character which may come to expression in fits of temper. The author mentions two forms of hypoglycemic symptoms which he found in his practice. The first was in a boy aged 9 who had no appetite and could not concentrate at school. When his attention was requested he became impolite and was punished. On returning home from school he would lie down complain of being tired, look pale and have cold sweat on the forehead. Then he would be somewhat nauseated and unable to eat although he was hungry shortly before. A couple of sugar tablets dispelled the attack and appropriate treatment resulted in giving the boy normal health and in making him a good scholar. The second form occurred in a young woman who was nursing a four months old baby and complained of pain between the scapulae and in the back and of feeling dizzy and nauseated after each nursing. Determination of blood sugar showed it to be 0.072 Gm. per hundred cubic centimeters before and 0.053 after nursing. A small amount of sugar taken before each nursing cured the symptoms and the back pain disappeared when the diet of the patient was regulated.

*Blood Metabolism and Urobilinuria in Cardiac Insufficiency M. C. Ehrström—p. 517

Influence of Heparin on Coagulation Time—Hedenius and Wilander say that, although many methods have been tried to lessen the risk of postoperative thrombosis, the most natural anticoagulant, heparin, has not been used for that purpose. They point out that heparin has so far been employed almost exclusively in animal experiments, because the available preparations were not pure enough for intravenous injections in human beings. In recent years it has become possible to obtain heparin in a fairly pure state. The authors used a protein-free, sterile, 5 per cent solution which contained approximately 0.25 per cent of tricresol. Before administering the substance to patients, the authors made preliminary experiments on rabbits and on themselves. The investigations revealed that the intravenous injection of heparin (from 50 to 150 mg.) results in normal persons in a considerable prolongation of the coagulation time. Different persons react fairly uniformly to the same dose of heparin. The prolongation of the coagulation time is not quite proportional to the dose of heparin, in that the effect of smaller doses is relatively stronger. By repeated injections of small doses of heparin (from 50 to 25 mg. every three hours) a prolonged heparin effect can be obtained. The treatment with heparin seemed to cause no objective or subjective disturbances.

Sedimentation Reaction with Heparin—Enochsson and his associates have investigated in what relation the sedimentation reaction with heparin has an advantage over that with citrate. They reach the conclusion that the heparin sedimentation reaction represents the actual sedimentation reaction, is more sensitive than that which is made with citrate, and has the advantage that the necessity for a special syringe is done away with, if necessary the blood can be taken from a puncture in the finger, or in some other way, when there is any difficulty in obtaining venous blood. Against these advantages hardly any drawbacks can be mentioned, except that the heparin test is more expensive than the citrate test. The appearance of lower sedimentation values with heparin than with citrate in cases of anemia and fever is comparatively rare. With a material of about 2,000 cases the authors gained the impression that these lower values in cases of the heparin test are often due to the use of too small amounts of heparin, so that coagulation is not completely inhibited. They are convinced that if this fact is taken into consideration the lower values with heparin will be rarely found.

Blood Metabolism and Urobilinuria in Cardiac Insufficiency—Ehrström studied the blood metabolism and the behavior of urobilinuria in ten patients with cardiac insufficiency. To obtain information about the metabolism of the blood he counted the reticulocytes, determined the volume of the blood, took an erythrocyte count, determined the hemoglobin content and examined the pigmentation of the serum. He determined the total elimination of urobilin and observed the urobilinuria. During the period of insufficiency there exists a true reticulocytosis which, however, subsides when compensation is achieved. This subsidence is accompanied by an increase in the total urobilin elimination. Expressed differently the blood metabolism of patients with cardiac insufficiency is characterized by an increased hematopoiesis during the period of insufficiency and an increased hemolysis during the subsidence of the insufficiency. The most probable cause of these changes in the blood metabolism is the anoxemia. The urobilinuria of patients with cardiac insufficiency shows such a pronounced parallelism to the urobilin elimination in the feces that it appears probable that the hemolysis is a dominating factor in the pathogenesis of the urobilinuria during cardiac insufficiency.

OBSERVATIONS ON INDUSTRIAL DERMATOLOGY

CHAIRMAN'S ADDRESS

HARRY R. FOERSTER, M.D.
MILWAUKEE

The evolution of industry during the present generation, with its associated changes in the social and economic status of labor, has effected related changes in medical practice in industrial communities. This has been brought about in part by industry itself in the interests of economy, efficiency and safety, and it has been regulated and promoted by governmental agencies in the interests of public health and political control. The management of industrial accidents and diseases today is a modified form of state medicine that is still in a transitional phase, subject to the directional influences of lay, legal and medical groups.

The need of organizing dermatologic information, study and activity in this field resulted in the creation of a committee for that purpose at the last session of the Section on Dermatology and Syphilology. In view of this, some observations on the economic, legal and medical status of industrial dermatology in the United States will be presented.

INCIDENCE

A proper understanding of the scope and importance of industrial dermatology requires a brief review of the economic considerations. Complete and accurate figures on industrial skin diseases are not available, because few states record them and then only when five or more more days of disability for work has occurred. Nondisabling dermatoses, always a large group, are not available for study, except where legally reportable. The following information is authoritative however, having been obtained through the cooperation of public officials of the individual states and the federal government.

The United States census of 1930 listed nearly 49 million individuals in gainful occupations, of whom approximately 4 million were in public and professional service, 5 in domestic and personal employment, 10 in agricultural pursuits and 25 in trade, transportation, communications, and in manufacturing, mechanical and mining industries. It is chiefly this last group of 25 million that is subject to compensation laws, though in some states practically all employees, excepting farm and home help, are covered. Workmen's compensation acts usually apply to all employers of five or more employees.

The United States Department of Labor¹ lists 928 hazardous occupations, inclusive of 122 of the more common activities in which skin diseases are prone to develop. There are also numerous unlisted industries and occupations in which skin diseases occur. In the states where figures are available the incidence of dermatoses is uniformly high. In a single year (1934) six states (California, Connecticut, Ohio, Massachusetts, Wisconsin and Missouri) recorded 4,500 cases of disabling dermatoses, or 68 per cent of the total number of occupational diseases. In a three-year period Ohio statistics showed that there was no compensable disability in 61 per cent of the claims filed for occupational skin diseases.

During the first six years that occupational diseases were legalized as compensable in Ohio, 4,400 claims were filed, of which 3,000 were because of skin disease. Dermatitis was stated as the cause of disability in 2,900 claims, and the total group of skin diseases was responsible for a loss of 86,000 work days, in addition to five fatalities and two permanent disability claims.²

That the numerical superiority of occupational dermatoses over other industrial diseases may not unduly exaggerate their importance, it should be stated that the total number of compensable occupational diseases constitutes only from 1 to 3 per cent of the total number of compensated occupational injuries and diseases.

For example, in 1934 Massachusetts recorded 35,200 disabling injuries and diseases, of which 700, or 2 per cent, were occupational diseases, 493 cases or less than 1.5 per cent of the total, were dermatoses.³

Schwartz⁴ of the United States Public Health Service examined 18,000 workers in rubber industries, oil refineries, dyeing establishments and candy factories and found 235 cases of occupational dermatoses among active employees at the time of examination, an incidence of 1.5 per cent. He believes that more than 1 per cent of the workers engaged in basic industries are annually affected by dermatoses. In a chemical and dye plant with 2,500 employees he observed during one year an incidence of 16 per cent of chemical burns and dermatitis. An even higher disease incidence was observed in work with synthetic waxes and resins,⁵ in one factory it reached 50 per cent. This is in line with the observation that the newer the industry and the newer the chemical compounds, the greater will be the number of cases of dermatitis, because of unknown

and unfamiliar hazards, lack of protective measures, and lack of adaptation on the part of the employee to the work.

A careful compilation of statistics on occupational dermatoses should be sought by this section because of its economic value in directing attention to the need of instituting preventive measures against dermatoses and improving their diagnosis and treatment. Massachusetts, Connecticut and Ohio are the only states that have made a satisfactory approach to this subject.

LEGISLATION

Compensation laws are a recent development in this country, and the trend of the times is evident in the broadening of the scope of such laws in eight states in the last two years.

The first provision for compensation of injured employees in the United States was established in 1908 for the federal civil service. In 1911 the Wisconsin legislature established the first workmen's compensation act to deal with industrial injuries.⁶ In rapid order several other states enacted similar laws and since then there has been a gradual increase in such enactments.

Our compensation laws were based on older European "codes" but have become broader in their scope and have been more liberally interpreted by commissions and courts, and, in the opinion of Jones,⁷ they "have been much more precipitate, ill considered, diversified and variant." Jones states also that "under the compensation laws of this country, differing from nearly all foreign precedents, claims for occupational disease, where covered by such laws are determined by laymen everywhere regardless of the weight of medical evidence, the claimant receiving the benefit of doubt if there be any medical opinion or testimony in favor of the validity of a claim."

Workmen's compensation legislation in this country applied originally to occupational injuries only, and in more than twenty-four states this restriction still holds good, though a number of states have broadened their interpretation of the word "injury." Eight states (Colorado, Georgia, Iowa, Montana, Maryland, Pennsylvania, Texas, and Washington) specifically exclude occupational diseases from their compensation provisions though a few exceptions are made.

In 1919 the Wisconsin legislature defined "injury" under the workmen's compensation act as "mental or physical harm caused by accident or disease," since which time it has been necessary only to establish an occupational origin for a disease to legalize a compensation claim in Wisconsin.

Eight states (Alabama, Maine, Nevada, Oregon, Tennessee, West Virginia, Virginia and Rhode Island), without specific laws regarding occupational disease, recognize the compensability of dermatoses when caused by or aggravated by injury.

The industrial commission of Nevada has allowed compensation for dermatitis when it could be reasonably interpreted that the dermatitis arose from an injury or an accumulation of injuries or from trauma caused by continued irritation. The Oregon state industrial accident commission holds that "occupational diseases are not compensable since they are not due to injury by accident received through violent or external means as defined by the law, and yet the courts of Oregon have compelled payment of compensation in a

large number of cases of dermatitis from poison ivy, hemlock, spruce, hop and fruit on the theory that the exciting cause of dermatitis in such cases is an abrasion or minor injury.

Six states (Kansas, Ohio, New Jersey, Nebraska, North Carolina and Minnesota) specifically restrict compensation for occupationally acquired dermatoses to listed or scheduled occupations, listed diseases, or contacts with listed substances. This has resulted in errors of omission and commission and in certain absurd rulings.

New Jersey has compensated for dermatitis when it could be shown that "the worker had contracted an occupational substance covered by the occupational disease act." Minnesota legalizes compensation for dermatitis from African boxwood and recognizes only twenty-two other occupational diseases and causes of occupational disease. In Nebraska compensation is limited to diseases in the lead and zinc industries, though recognition is given to the aggravation of pre-existing disease by accidental injury. Ohio's schedule of twenty-one occupational diseases is quite inclusive and meets the major industrial disease problems of that state.

Arkansas and Louisiana have no compensation laws for either injury or disease.

The 1935 New Hampshire legislature provided for a commission of three physicians, three representatives of labor and three representatives of industry, to study the compensation laws and occupational disease situation in that state. Michigan, Idaho and Maryland have provided for similar investigations.

Eight states (Illinois, California, Connecticut, Massachusetts, North Dakota, Missouri, New York and Wisconsin) and Hawaii and the Philippines have what is called "blanket legislation." New York joined this group in 1935 and Illinois in 1936, and the Rhode Island legislature has a "blanket provision" under consideration at this time. The "blanket" provides compensation for any disabling disease, dermatosis included, arising out of an individual's occupational activities. Predisposition to dermatitis is no bar to compensation in such cases.

In Missouri any skin disease directly traceable to an employee's work is compensable under the law, "provided both employer and employee are operating under that particular phase of the law." In Connecticut, occupational disease is defined as "a disease peculiar to the occupation in which the employee was engaged and due to causes in excess of the ordinary hazards of employment as such." Interpretations have been liberal. The Connecticut law also states that in case of aggravation of a preexisting disease, compensation shall be allowed only for such proportion of the disability as may be reasonably attributed to the injury on which the claim is based.⁸

There is much to be said both in commendation and in criticism of our laws, as regards their provisions, interpretation and enactments. Under both schedules and blanket provisions the opportunity exists for injustice to both employer and employee, and the variability of the laws in different states, and the greater variability and uncertainty of their interpretation by the courts constitute a constant hazard to the financial security of some industries and their insurance carriers. Legal provisions for nondisabling injuries and diseases are usually lacking or vaguely defined.

⁶ Industrial Compensation in Wisconsin, 1934.
⁷ *Ind. Eng. Chem. Anal. Ed.* 4: 222 (April 1932).

⁸ Bull. 13, Connecticut Workmen's Compensation, 1935.

The recognition of compensability of industrial injuries, which are sometimes the result of carelessness by the worker, and the denial of compensation for occupationally acquired disease, for the acquisition of which the employee is usually not responsible, are legal anachronisms that should not be permitted to exist. The same criticism applies to the restriction of compensation to listed or scheduled occupations, diseases or substances, it being recognized by dermatologists that almost any trade or occupation, and any irritant, may be the source of a dermatosis in a susceptible individual. The important legal consideration is obviously not the type of occupation, nor the nature of the irritant, but the relationship of both irritant and occupation to the acquisition or aggravation of the dermatosis. "Schedules" provide a legal crutch that may be used to bar a legitimate award for compensation or to support an unjust claim. It permits the lawyer to settle the question of compensability on the basis of names, whereas it should be the physician who determines the liability on a basis of etiology and the law that decides the case on the evidence presented.

In a recent article on the medicolegal aspects of occupational dermatoses, Sulzberger⁹ has directed criticism at laws that permitted the awarding of compensation without reasonable proof of the causal connection between the occupation and the existing dermatosis.

MEDICAL SUPERVISION

In reviewing the compensation laws of the states, I have been impressed with the almost complete absence of provision for participation by the medical profession in the designing and enactment of the various laws and the provisions for their application and interpretation.

The industrial accident commissions of California, Iowa, Nevada and Washington have medical directors or advisers. In Massachusetts¹⁰ the industrial accident board submits claims for compensation to a board of three physicians, known as industrial disease referees, who are individually selected for each case from a list of registered physicians furnished by the state board of medical registration. In all other states, lay boards have exclusive jurisdiction over compensation and pass judgment on controversial cases.

As this question applies to dermatology, I am heartily in accord with the opinion expressed by Sulzberger⁹ "that compensation laws will more adequately do justice to occupational dermatoses only when they are formulated with the advice and collaboration of competent dermatologists." I also agree with him "that an employee be entitled to compensation only when his occupation can be proven, beyond reasonable doubt, to be, directly or indirectly, a causal or contributory factor in the production of the dermatosis, and that compensation be commensurate with the degree to which the occupation is responsible for the skin disease."

State boards of health, concerned primarily with disease prevention, have supervision over industrial accidents and disease in only eight states.

Physicians in Ohio and Connecticut are required by law to report to the director of health all diseases and disabilities contracted as a result of the nature of the patient's employment. The Connecticut health department has a bureau of occupational diseases which makes surveys and field studies, secures and compiles reports of occupational diseases, provides consultation and

information for physicians and industry, and renders reports of its conclusions and recommendations to industry.¹¹ Michigan has just created a department of industrial hygiene within its health department.

There appears to be a very definite need for closer cooperation between legislative bodies and organized medicine for disease prevention and control, the realization of which should not be difficult in view of common aims. The United States Public Health Service and the respective state boards of health, not being engaged in competitive medical practice, appear to be the logical bodies for such cooperation and could do much toward the accumulation of valuable data, the dissemination of information and the endorsement of remedial legislation in the field of industrial dermatology. This section may safely sponsor a program along these lines.

Considering the advance that has been made in many states toward the recognition of occupational diseases, when previously only injuries were judged compensable, we may anticipate the recognition of the right of compensation of all industrial diseases in all states, with consequent elimination of archaic schedules or "listing." I believe that we, as a representative dermatologic group, may advisedly endorse the type of workmen's compensation legislation now prevailing in those states with "blanket legislation," recognizing however the dangers inherent in such liberal laws, and the need of certain modifications and restrictions. I believe that some form of medical control over occupationally acquired diseases should be legally provided and that occupational dermatoses should be under dermatologic supervision. This section should recognize the desirability and need of dermatologic direction of legislative procedure pertaining to dermatoses and should take action as spokesman for this specialty.

INTERPRETATION

The practice of defining occupational diseases by naming or specifically describing them for "listing or scheduling," and of restricting compensation to diseases falling in such classifications is a European custom, and it is favored by insurance carriers in this country. The chief arguments in its favor are based on an apparently smaller margin of error in diagnosis and compensation awards, because of restriction of liability to industries in which there is a particular disease hazard. It is not however in the best interests of the worker, and the increasing complexity and development of industry constantly introduces new factors in disease production that would require frequent revision of schedules through legislative action. "Blanket laws," on the other hand, penalize industry in that under their provisions many cases recognized as occupational dermatoses are not due, or not solely due, to the industry but result from some act or predisposition of the patient foreign to the employment.

The wide abuse, through incompetent medical and legal interpretations, observed to follow progressive liberalization of industrial disease legislation, is not a valid argument against such legislation but speaks for the greater need of expert diagnosis and experienced medical management.

As the responsibilities of the physician increase, our responsibilities as dermatologists involve the extension and unification of dermatologic knowledge and opinion. James C. and C. J. White, C. Guy Lane, Knowles Cole,

and unfamiliar hazards, lack of protective measures, and lack of adaptation on the part of the employee to the work

A careful compilation of statistics on occupational dermatoses should be sought by this section because of its economic value in directing attention to the need of instituting preventive measures against dermatoses and improving their diagnosis and treatment. Massachusetts, Connecticut and Ohio are the only states that have made a satisfactory approach to this subject

LEGISLATION

Compensation laws are a recent development in this country, and the trend of the times is evident in the broadening of the scope of such laws in eight states in the last two years

The first provision for compensation of injured employees in the United States was established in 1908 for the federal civil service. In 1911 the Wisconsin legislature established the first workmen's compensation act to deal with industrial injuries.⁶ In rapid order several other states enacted similar laws and since then there has been a gradual increase in such enactments

Our compensation laws were based on older European "codes" but have become broader in their scope and have been more liberally interpreted by commissions and courts, and, in the opinion of Jones,⁷ they "have been much more precipitate, ill considered, diversified and variant." Jones states also that "under the compensation laws of this country, differing from nearly all foreign precedents, claims for occupational disease, where covered by such laws, are determined by laymen, everywhere regardless of the weight of medical evidence, the claimant receiving the benefit of doubt if there be any medical opinion or testimony in favor of the validity of a claim"

Workmen's compensation legislation in this country applied originally to occupational injuries only, and in more than twenty-four states this restriction still holds good, though a number of states have broadened their interpretation of the word "injury." Eight states (Colorado, Georgia, Iowa, Montana, Maryland, Pennsylvania, Texas, and Washington) specifically exclude occupational diseases from their compensation provisions, though a few exceptions are made

In 1919 the Wisconsin legislature defined "injury" under the workmen's compensation act as "mental or physical harm caused by accident or disease" since which time it has been necessary only to establish an occupational origin for a disease to legalize a compensation claim in Wisconsin

Eight states (Alabama, Maine, Nevada, Oregon, Tennessee, West Virginia, Virginia and Rhode Island), without specific laws regarding occupational disease, recognize the compensability of dermatoses when caused by or aggravated by injury

The industrial commission of Nevada has allowed compensation for dermatitis when it could be reasonably interpreted that the dermatitis arose from an injury or an accumulation of injuries or from trauma caused by continued irritation. The Oregon state industrial accident commission holds that "occupational diseases are not compensable since they are not due to injury by accident received through violent or external means" as defined by the law, and yet the courts of Oregon have compelled payment of compensation in a

large number of cases of dermatitis from poison ivy, hemlock, spruce, hop and fruit on the theory that the exciting cause of dermatitis in such cases is an abrasion or minor injury

Six states (Kansas, Ohio, New Jersey, Nebraska, North Carolina and Minnesota) specifically restrict compensation for occupationally acquired dermatoses to listed or scheduled occupations, listed diseases, or contacts with listed substances. This has resulted in errors of omission and commission and in certain absurd rulings

New Jersey has compensated for dermatitis when it could be shown that "the worker had contracted an occupational substance covered by the occupational disease act." Minnesota legalizes compensation for dermatitis from African boxwood and recognizes only twenty-two other occupational diseases and causes of occupational disease. In Nebraska compensation is limited to diseases in the lead and zinc industries, though recognition is given to the aggravation of pre-existing disease by accidental injury. Ohio's schedule of twenty-one occupational diseases is quite inclusive and meets the major industrial disease problems of that state

Arkansas and Louisiana have no compensation laws for either injury or disease

The 1935 New Hampshire legislature provided for a commission of three physicians, three representatives of labor and three representatives of industry, to study the compensation laws and occupational disease situation in that state. Michigan, Idaho and Maryland have provided for similar investigations

Eight states (Illinois, California, Connecticut, Massachusetts, North Dakota, Missouri, New York and Wisconsin) and Hawaii and the Philippines have what is called "blanket legislation." New York joined this group in 1935 and Illinois in 1936, and the Rhode Island legislature has a "blanket provision" under consideration at this time. The "blanket" provides compensation for any disabling disease, dermatosis included, arising out of an individual's occupational activities. Predisposition to dermatitis is no bar to compensation in such cases

In Missouri any skin disease directly traceable to an employee's work is compensable under the law, "provided both employer and employee are operating under that particular phase of the law." In Connecticut, occupational disease is defined as "a disease peculiar to the occupation in which the employee was engaged and due to causes in excess of the ordinary hazards of employment as such." Interpretations have been liberal. The Connecticut law also states that, in case of aggravation of a pre-existing disease, compensation shall be allowed only for such proportion of the disability as may be reasonably attributed to the injury on which the claim is based.⁸

There is much to be said both in commendation and in criticism of our laws, as regards their provisions, interpretation and enactments. Under both schedule and blanket provisions the opportunity exists for injustice to both employer and employee, and the variability of the laws in different states, and the greater variability and uncertainty of their interpretation by the courts constitute a constant hazard to the financial security of some industries and their insurance carriers. Legal provisions for nondisabling injuries and diseases are usually lacking or vaguely defined

⁷ Jones, F. R. *Industrial Med.* 4: 222 (April) 1935

⁸ *Bull. 13 Connecticut Workmen's Compensation, 1935*

The recognition of compensability of industrial injuries, which are sometimes the result of carelessness by the worker, and the denial of compensation for occupationally acquired disease, for the acquisition of which the employee is usually not responsible, are legal anachronisms that should not be permitted to exist. The same criticism applies to the restriction of compensation to listed or scheduled occupations, diseases or substances, it being recognized by dermatologists that almost any trade or occupation, and any irritant, may be the source of a dermatosis in a susceptible individual. The important legal consideration is obviously not the type of occupation, nor the nature of the irritant, but the relationship of both irritant and occupation to the acquisition or aggravation of the dermatosis. "Schedules" provide a legal crutch that may be used to bar a legitimate award for compensation or to support an unjust claim. It permits the lawyer to settle the question of compensability on the basis of names, whereas it should be the physician who determines the liability on a basis of etiology and the law that decides the case on the evidence presented.

In a recent article on the medicolegal aspects of occupational dermatoses, Sulzberger⁹ has directed criticism at laws that permitted the awarding of compensation without reasonable proof of the causal connection between the occupation and the existing dermatosis.

MEDICAL SUPERVISION

In reviewing the compensation laws of the states, I have been impressed with the almost complete absence of provision for participation by the medical profession in the designing and enactment of the various laws and the provisions for their application and interpretation.

The industrial accident commissions of California, Iowa, Nevada and Washington have medical directors or advisers. In Massachusetts¹⁰ the industrial accident board submits claims for compensation to a board of three physicians, known as industrial disease referees, who are individually selected for each case from a list of registered physicians furnished by the state board of medical registration. In all other states, lay boards have exclusive jurisdiction over compensation and pass judgment on controversial cases.

As this question applies to dermatology, I am heartily in accord with the opinion expressed by Sulzberger⁹ "that compensation laws will more adequately do justice to occupational dermatoses only when they are formulated with the advice and collaboration of competent dermatologists." I also agree with him "that an employee be entitled to compensation only when his occupation can be proven, beyond reasonable doubt, to be, directly or indirectly, a causal or contributory factor in the production of the dermatosis, and that compensation be commensurate with the degree to which the occupation is responsible for the skin disease."

State boards of health, concerned primarily with disease prevention have supervision over industrial accidents and disease in only eight states.

Physicians in Ohio and Connecticut are required by law to report to the director of health all diseases and disabilities contracted as a result of the nature of the patient's employment. The Connecticut health department has a bureau of occupational diseases which makes surveys and field studies, secures and compiles reports of occupational diseases, provides consultation and

information for physicians and industry, and renders reports of its conclusions and recommendations to industry.¹¹ Michigan has just created a department of industrial hygiene within its health department.

There appears to be a very definite need for closer cooperation between legislative bodies and organized medicine for disease prevention and control, the realization of which should not be difficult in view of common aims. The United States Public Health Service and the respective state boards of health, not being engaged in competitive medical practice, appear to be the logical bodies for such cooperation and could do much toward the accumulation of valuable data, the dissemination of information and the endorsement of remedial legislation in the field of industrial dermatology. This section may safely sponsor a program along these lines.

Considering the advance that has been made in many states toward the recognition of occupational diseases, when previously only injuries were judged compensable, we may anticipate the recognition of the right of compensation of all industrial diseases in all states, with consequent elimination of archaic schedules or "listing." I believe that we, as a representative dermatologic group, may advisedly endorse the type of workmen's compensation legislation now prevailing in those states with "blanket legislation," recognizing however the dangers inherent in such liberal laws, and the need of certain modifications and restrictions. I believe that some form of medical control over occupationally acquired diseases should be legally provided and that occupational dermatoses should be under dermatologic supervision. This section should recognize the desirability and need of dermatologic direction of legislative procedure pertaining to dermatoses and should take action as spokesman for this specialty.

INTERPRETATION

The practice of defining occupational diseases by naming or specifically describing them for "listing or scheduling," and of restricting compensation to diseases falling in such classifications is a European custom, and it is favored by insurance carriers in this country. The chief arguments in its favor are based on an apparently smaller margin of error in diagnosis and compensation awards, because of restriction of liability to industries in which there is a particular disease hazard. It is not however in the best interests of the worker, and the increasing complexity and development of industry constantly introduces new factors in disease production that would require frequent revision of schedules through legislative action. "Blanket laws," on the other hand, penalize industry in that under their provisions many cases recognized as occupational dermatoses are not due, or not solely due, to the industry but result from some act or predisposition of the patient foreign to the employment.

The wide abuse, through incompetent medical and legal interpretations, observed to follow progressive liberalization of industrial disease legislation, is not a valid argument against such legislation but speaks for the greater need of expert diagnosis and experienced medical management.

As the responsibilities of the physician increase, our responsibilities as dermatologists involve the extension and unification of dermatologic knowledge and opinion. James C. and C. J. White, C. Guy Lane, Knowles Cole,

Hazen and Pusey were among the pioneers in this field in the United States.¹² Recent valuable contributions have been made by Downing,¹³ Eller and Schwartz,¹⁴ Osborne and Putnam,^{14a} and other members of this section, and in Europe particularly by R. Prosser White¹⁵ and by Ullmann, Oppenheim and Rille.¹⁶

Occupational skin diseases actually constitute only a small percentage of all skin diseases, and it should be evident that a broad knowledge of dermatology is essential to maintain a proper balance in the interpretation of cases and the evaluation of observations. In the practice of most dermatologists with experience in industrial disease, occupational dermatoses aggregate less than 10 per cent of the total practice.

My associates and I recorded over 1,400 cases of occupational dermatoses in private practice in fifteen years, an average of 5 per cent.

Preexisting and coexistent dermatoses must be properly evaluated as regards their part in the development or prognosis of an occupational dermatosis. A judicious outlook in arriving at a diagnosis in a case with occupational implications is important, as emphasized by O'Donovan.¹⁷ All the evidence must be carefully weighed and too much credence must not be placed in the history furnished by the patient, which may be at variance with the facts. A general knowledge of factory conditions and a specific knowledge of the individual's work and working environment is of value and sometimes is necessary for diagnosis.

One of the chief causes of controversial legal procedure in certain types of dermatoses is the failure to obtain early expert dermatologic examination and treatment. Insurance carriers must become cognizant of the economic importance of the early observation and care of certain industrial cases by the specialist and of the need of closer cooperation between practitioner and specialist.

CAUSES

The etiology and symptomatology of occupational dermatoses have been exhaustively discussed in previous papers¹⁸ and will not be elaborated on at this time.

The majority of industrial dermatoses in this country are cases of contact dermatitis and are due to acids, alkalis, caustics, oils, greases and solvents. The causes as well as the incidence exhibit great variability in different states, dependent on the types of industries and the preponderance of industrial activities.

Schwartz's⁴ investigations in 1935 disclosed that the majority of occupational dermatoses were caused by alkalis and petroleum derivatives in New York, by lime, cement and plant poisons in Missouri, and by plant poisons and by mercury used in the hat industry in Connecticut, while in Ohio the majority occurred in the rubber industries and in workers with oils and cutting compounds.

A nonoccupational origin should always be sought for in cases of supposed trade dermatitis, it being too commonly assumed that a dermatitis, particularly a

dermatitis venenata, has resulted from the work. This occupation is one in which dermatitis is prevalent. A potent cause of occupational dermatitis that is often overlooked and that is entirely preventable is the use of turpentine, benzene and abrasive soaps in the removal of paint, grease and dirt.

DERMATOMYCOSES

Fungous and bacterial infections and allergic conditions represent some of the most important diseases that frequently cause confusion in diagnosis and prognosis. Of the dermatomycoses, epidermophytosis and monilia are of sufficiently frequent occurrence in industrial workers to present an important problem in diagnosis. Many laborers have intertriginous dermatitis of the toes, due to sweating and lack of proper hygiene, and this condition, when associated with a dermatitis venenata of the hands, may be mistaken for an epidermophytosis with a phytid reaction. A diagnosis of fungous infection in an industrial worker should therefore be made with proper reservation, subject to microscopic or cultural confirmation or the results of an adequate therapeutic test. Direct fungous infection of the hands is less common and is more readily differentiated from dermatitis venenata and eczematoid dermatitis than the more frequent phytid reaction. While admitting the importance of excluding fungous infections in the differential diagnosis of dermatitis venenata, and while recognizing the possibility that such infection may predispose to the acquisition of a dermatitis venenata or may complicate an occupational dermatitis through secondary infection, I believe this issue has been adequately emphasized in the past not to require elaboration in this paper.

INFECTIOUS ECZEMATOID DERMATITIS

The recognition of infectious eczematoid dermatitis is always important, and particularly in those states that restrict compensation for dermatoses to conditions arising out of industrial injuries. This disease is frequently observed both as a direct complication of injury and as the result of improper medical management of injuries. It is responsible for prolongation of disability and not infrequently for the development of a generalized, resistant eczematoid dermatitis.

DERMATITIS VENENATA AND CONTACT ALLERGY

Allergy plays a predominant role in industrial dermatology and accounts for some of the most difficult problems in this field. The majority of occupational dermatoses are cases of dermatitis, and the largest number of these, and the most clearly defined, belong in the dermatitis venenata or contact dermatitis group. Some of the cases of the latter group are examples of direct toxic action of chemical irritants on normal skin, others are cases of epidermal allergy, and the distinction between the two is not always clear.

In those cases of contact dermatitis due to allergic factors the allergy is usually, if not always, acquired and the shock tissue is primarily the epidermis. The allergic state may be limited to certain areas of the epidermis. According to Coca¹⁹ there is probably present in the sensitized epidermal cells an antibody-like substance but there is apparently no antigenic function in the excitant, which is an allergen, and no antibody-antigen reaction. pure epidermal allergy rare in occupational disease and believes that altered cutaneous reactions of allergic type occurring through occupational sources cannot result from epidermal contact alone but involve a vascular mechanism

THE PATCH TEST

It is in these cases of contact dermatitis that the eczema or patch test is of value, but it must be emphasized that this test is not a short-cut to dermatologic knowledge and it should not be made the basis of a diagnosis. Correctly applied and intelligently interpreted, it may be very useful, but its widespread adoption for diagnosis, its loose acceptance by insurance companies, and the likelihood of faulty interpretations should result in the application of proper restrictions.

The most reliable test is that of actual working conditions, but this is usually contraindicated and is chiefly valuable in retrospect, as indicated at times by the history. Occupational trauma, sweating at work, and repeated exposures over periods of weeks and months are some of the factors in industry leading to skin sensitization that cannot be duplicated in patch testing.

The hypersensitivity that resulted in a dermatitis is often confined to the area of dermatitis, and a patch cannot be applied to that site until long after recovery. If the material used in a test is in stronger concentration than existed in the occupational exposure or is in contact over a more prolonged period of time, or if it is applied to an area of localized hypersensitivity, a false positive reading may be obtained. The opposite condition may result negatively. In cases of positive patch test reactions, negative control tests in normal subjects, made under identical conditions, are important. Schwartz has pointed out that after a person has recovered from a dermatitis he may have become immune to the causative substances and yield a negative patch test, and also that if a polyvalent sensitivity has been developed the tested individual may react positively to a great variety of test materials not concerned in the development of the dermatitis.

Field and Sulzberger²¹ have recently shown that the result of a patch test may depend on the site chosen for the testing and on the time of application of the test or phase of sensitivity of the individual, and they warn against basing positive conclusions on one or a few patch tests, particularly if applied at the same time. Their experiments showed that variations in response to testing seemed to depend on chronological fluctuations in degree of sensitivity, which varied greatly at different times in one and the same area and they also showed that certain irregularly disseminated circumscribed skin areas seemed consistently less sensitive than others.

ATOPIC DERMATITIS

In atopic dermatitis (allergic eczema) the primary shock tissue is the vascular structure of the cutis and the epidermis becomes secondarily involved. There appears to be a hereditary abnormality of the cutaneous shock tissue in this group and the affected individual may possess a polyvalent sensitivity that results in acute attacks of dermatitis or in aggravations of existing dermatitis, following irritant occupational exposures.

Commonly developing in infancy or childhood and then becoming latent to appear again in early adult life, atopic dermatitis may readily be mistaken for occupational dermatitis. Many of these cases recur or exacerbate at an age when young men and women leave

school to enter industry, and this frequently occurs in autumn, when seasonal factors such as pollen exposures and cold weather may aggravate atopic dermatitis.

Even when it exists, a history of atopy may be difficult or impossible to obtain, particularly from a foreign-born laborer. The worker will admit a history of occupational aggravation more readily than he will disclose a preexisting dermatitis, hay fever or asthma, and if he had an infantile eczema he probably does not know it. Exposed surfaces of the upper extremities, face and neck are usually the sites of predilection for both atopic dermatitis and occupational dermatitis. After either condition has been active for weeks or months it defies dermatologic acumen to determine the etiology. A hereditary atopic dermatitis aggravated by irritant occupational contacts, may yield a positive patch test to occupational materials and thus result in further confusion.

Disabling chronic dermatitis, intractable to appropriate treatment and showing no tendency to recover after prolonged removal from the supposed occupational cause, should always be looked on with suspicion as possibly having been originally a nonoccupational allergic condition.

CHRONIC ECZEMA

Cases of eczematoid dermatitis in which the primary attack was due to a specific occupational sensitization, and in which frequent relapses or recurrences resulted in the development of a chronic eczema that continued indefinitely after discontinuance of employment, are the result of a gradually developed nonspecific polyvalent cutaneous sensitivity to substances come in contact with in daily life. Such cases may be further complicated by secondary bacterial and fungous infections and result in confusion with Coca's infectious allergic dermatitis.

Some cases of intractable chronic eczema of occupational origin, continuing indefinitely after removal from work, occur in elderly employees, of impaired or mediocre physical stock, with obscure foci of infection, degenerative changes in vital organs or defective metabolic processes, all of which contribute to the prolongation of dermatitis and disability.

Cases of this type are usually not seen by the dermatologist until it is too late to determine the etiology with certainty or until polyvalent sensitivities and other complications have rendered them intractable to treatment. Whether or not a case of this nature originated as an occupational dermatitis, the employer or insurance carrier can no longer escape liability. Obviously there is liability, but likewise not sole responsibility, of the employer.

How are these cases to be interpreted and managed? Probably a legal limit should be established for total disability payments in such cases, based on an appraisal of the occupational factor, though from a humanitarian point of view these patients should be cared for as chronic invalids. In several states where public funds are used to meet occupational disability payments the problem can be solved by the establishment of pension funds. Where private corporations and private insurance carriers hold sole financial responsibility for such cases, the present controversy over awards will continue until the laws are changed. In the adjustment of such cases the medical expert will play a responsible role, requiring an intimate knowledge of medical interpretation and analysis.

²¹ Field, Hans and Sulzberger. *M. B. J. Allergy* 7: 139 (Jan.) 1936.

CONCLUSION

Since the dermatologist possesses the basic knowledge essential for the proper interpretation and solution of many problems in skin diseases confronting industry, he should prepare himself to cope intelligently with them in cooperation with others, and he should be called on to exercise the functions of an expert.

The industrial dermatoses committee of this section has before it the opportunity of clarifying and unifying dermatologic knowledge and opinion on industrial dermatology, and in that way of further advancing industrial medicine and the proper participation of individual dermatologists in such progress.

NEURALGIAS AND EAR SYMPTOMS

ASSOCIATED WITH DISTURBED FUNCTION OF THE
TEMPOROMANDIBULAR JOINT

JAMES B. COSTEN, M.D.
ST. LOUIS

When this group of pain symptoms and deafness were proposed¹ in 1933 as comprising a symptom complex regularly associated with destruction of the mandibular joint, it was considered as not rare but of infrequent occurrence. Deductions were made from cases presenting an edentulous mouth and extensive destruction of the joint, showing wide overclosure of the jaw. In the first small group there appeared patients with unilateral loss of molar support, however, which demonstrated the pain qualities more clearly and responded more promptly to the proposed solution of the problem, that is, the replacement of adequate molar support on the affected side.

During a two year period the study of these cases was continued, and they were drawn not only from a group referred as sinus and ear cases but also from those being studied in dermatology, internal medicine and neurosurgery. The number of proved cases having reached 125, their occurrence may now be considered very common. It was shown that ear symptoms predominate in patients with edentulous mouths whose symptoms develop slowly as a pressure effect on eustachian tubes and that pain symptoms, with or without herpes of the external canal and buccal mucosa, predominate in the cases of natural malocclusion or malocclusion from loss of molar support on one side only. A few patients with apparently perfect natural teeth were definitely relieved by extension of the joint the very minimal amount of 2 to 4 mm., accomplished by the use of an overlay on the molar teeth. A majority, eighty-nine patients, were above 40 years of age, the largest group being between the ages of 50 and 60 years. Each decade of life results in more wear of the natural teeth or loss of them, with the potential chance of destruction of the mandibular joint.

Some or all of the following symptoms were regularly found associated with these cases of malocclusion.

The ear symptoms were intermittent or continuously impaired hearing, stopping or "stuffy" sensation in the ears, marked about meal time, tinnitus, usually "low

buzz" in type, less often a snapping noise while chewing, dull or "drawing" pain within the ears, and dizziness, with nystagmus.

The pain and irritative symptoms were headache about the vertex and occiput and behind the ear, typical site of posterior sinus pain, increasing toward the end of the day (atypical sinus history and suggestive of eye headache), burning sensation in the throat, tongue and side of the nose, dry mouth with almost total absence of saliva and, rarely, excessive saliva, occasional herpes of the external ear canal and buccal mucosa, most marked on the edentulous side.

The chief function of the jaw being mastication, it is equipped with powerful muscles, the masseter, the temporalis, the pterygoideus internus, all of whose function it is to close the jaw. Acting as openers are the factors of the external pterygoid action, the action of the digastric muscle and the natural weight of the jaw. By complicated interaction, the jaw is fixed to aid in the act of swallowing, moves to a varying extent to accommodate the production of speech, and adapts itself to great variations produced by densities of food, yawning, laughter, and so on. The extent of normal opening of the jaw is controlled by the sphenomandibular ligament, the stylomandibular ligament and the short temporomandibular ligaments making up the capsule of the mandibular joint. The latter being weak at the forward aspect, extreme looseness sometimes permits the condyle to slide entirely beyond the articular eminence, producing subluxation of the jaw. The extent of closure of the jaw is determined by the teeth. Since most of the power of the muscles of mastication is applied to the posterior third of the jaw, most of the impact of chewing is taken by the molar teeth, very little being applied in the incisor district, the mandibular joint acting only as a weak hinge or guide to this movement.

It is not surprising therefore, when molar teeth are missing or the vertical dimension of the jaw is abnormally reduced by shrinkage of the alveolar ridge beneath plates or by grinding away of the natural teeth, that the mandibular joint should assume an unaccustomed burden from this district and much of its structure destroyed. When this occurs some of the force is thrown into the incisor region, but most of it is referred upward to the mandibular joint in direct line of the vertical dimension of the jaw. Proper regard for this function is the basis for testing the patient for the mandibular joint "syndrome" and is the basis on which the dentist proceeds to restore the position of the jaw.

The most common symptom observed was headache. Sixty-three patients had regular daily headache, more or less severe, forty-nine of whom described the pain as vertex, occipital and about the ears. Twelve had only supra-orbital pain. All these presented themselves or were referred for study as sinus cases. Almost all showed more or less sinus infection, for which proper treatment was given. Thirteen volunteered the description of pain as increasing toward the end of the day. This was typical of eyestrain headache, and no eye lesions were found. The distribution of pain was quite typical of posterior sinus disease.

In a previous report,¹ anatomic reasons were advanced for the pain, i. e. (1) erosion of the bone of the glenoid or mandibular fossa, and impaction of the condyles against the thin bone separating them from the dura, (2) irritation by the uncontrolled movement of the condyles backward or mesially, of the auriculo-

From the Department of Otolaryngology, Washington University School of Medicine and the Oscar John on Institute.

1 Costen, J. B. A Syndrome of Ear and Sinus Symptoms Dependent upon Disturbed Function of the Temporomandibular Joint. *Ann. Otol. Rhin. & Laryng.* 45: 1 (March) 1937.

temporal nerve, which passes intimate to the mesial side of the capsule between the condyle and the tympanic plate to distribute over the temporal and vertex region, (3) production of reflex pain and sensory disturbance in the various connections of the chorda tympani nerve, the condyle irritating it where it emerges from the tympanic plate at the mesial edge of the glenoid fossa through the petrotympanic fissure.

Reasoning from the fact that the mandibular joint capsule is weaker on the mesial side and the glenoid fossa is protected laterally by the zygoma, it was assumed that the condyle of the joint most affected would move mesially to impact the nerves, and the condyle of the opposite side would adapt itself downward or forward. It was also assumed that in unilateral loss of teeth the joint on the unsupported side would suffer most destruction. Observation of the jaw movements of this type of case showed that the patient attempts to occlude the remaining teeth by weaving the jaw laterally toward them. The lower teeth slip beyond the upper on occlusion, and the condyle on the unsupported side is pulled mesially and upward by the chewing muscles. Exactly the same thing happens when the natural teeth are worn or badly occluding and fail to take the impact of the chewing movement. The joint on the poorly supported side is destroyed. Its condyle slips mesially on closure, impacts the nerves and initiates pain on the same side. Twenty-one cases fall into this group, and the various pains invariably occur on the side in which proper molar support is entirely lost. The joint on the same side is usually quite tender to palpation internally and functions with a crunching noise. Ear symptoms such as stopping and deafness, are notably absent in these unilateral neuralgia cases.

Glossodynia, or burning tongue, has been described by Butlin,² Engman,³ Dean,⁴ Sluder⁵ and numerous others. Frequent reference is made to the complaint in cases of pernicious anemia, glossopharyngeal neuralgia and gastric diseases. Dean, and later Sluder, found that some of the cases could be relieved by injection of the nasal ganglion.

Twenty-two patients in this series described pain and sensory disturbances about the lateral pharyngeal wall and tongue. The emergence of the chorda tympani nerve at the mesial edge of the mandibular fossa was suggested¹ to account for sensory disturbance in the tongue, when irritated by the loose movement of the condyle mesially. Irritation of the auriculotemporal nerve, as described, may produce pain in the remaining branches of the mandibular nerve, one of the largest of which is the lingual nerve, supplying sensation to the anterior two thirds of the tongue. The afferent fibers represented by the chorda tympani nerve are actually the sensory part of the facial nerve and end, in part, in the same nucleus as does the ninth or glossopharyngeal nerve. These fibers are considered (Piersol) "as an aberrant strand of the glossopharyngeal." Under other circumstances of study these cases may have been regarded as glossopharyngeal neuralgia, the description of glossopharyngeal neuralgia usually is that it is a paroxysmal pain referred to the region of the fauces and lateral wall of the pharynx, often radiating up to

the ear on the affected side, case reports state that the trigger which starts the pain is the act of swallowing. With the mouth closed, as in swallowing, the mechanism for irritating both the chorda tympani and the auriculotemporal nerves by the condyle is ideal.

The evidence is convincing that malocclusion and destruction of the mandibular joint is important in the etiology of glossopharyngeal neuralgia. It is clear, since eighteen of the twenty-two cases of burning tongue were completely relieved by reposition of the jaw, that this is the principal etiologic factor of glossodynia of peripheral nerve origin.

A test was made in one patient who had complained of a copper and salt taste along the left border of the tongue for a period of four months, by wearing a cork pack 12 mm in thickness within the left molar spaces for forty-eight hours. She was completely relieved and the case was classified as an example of irritation of the left chorda tympani. She was sent to the dentist but refused to have a denture because she considered the condition entirely cured.

Herpes and salivary disturbance appear to be irritative phenomena. These occur frequently in the pain

Fig 1—Manner of testing suspected destruction of the mandibular joint. The two 2 mm disks are worn within the jaws an arbitrary period of from two days to one week. This schema shows the effect on the joint of widening the vertical dimension moving the condyle away from proximity to the nerves.

group and are invariably relieved when the pain factors are successfully removed. Salivary disturbance, usually inhibition with excessive dryness of the mouth, is constantly found in the cases presenting burning tongue.

Although herpes is established as a toxic disease of the ganglions of the posterior nerve roots associated with a vesicular inflammation of the skin of the corresponding areas, a mild type is found associated with these cases not occurring in the presence of acute infection. There were twenty-one patients in the series, all in the pain group, who described vesicular eruption about the external canals, the corners of the mouth, the hard palate or the buccal mucosa. In fifteen cases that were followed up this was relieved along with the other complaints. Hunt⁶ has pointed out a characteristic symptom complex: deep seated pain in the ear and mastoid, herpes of the auricle, the external auditory canal, and the tonsillar region, and also facial paralysis in connection with inflammation of the geniculate ganglion. He described certain cases presenting herpetic lesions about the external auditory canal, and

with pain symptoms but without facial palsy. He classed these as of the type of zoster of the auricle, long before termed idiopathic, these were accounted for by earlier observers favoring the neuritic theory of herpes zoster, by ascribing the skin lesions on the auricle to a neuritis of the auriculotemporal branch of the fifth nerve. The favorable reaction of the herpes group of this series to repositioning of the jaw is proof that their source is pressure irritation of the auriculotemporal and chorda tympani nerves by uncontrolled movements of the condyle and is transmitted to the ganglions. It would explain the idiopathic group referred to in Hunt's series, as well as the twenty-one cases just mentioned.

Fig. 2—The Spronll position is used in making films of the temporomandibular joints. The patient's head is tilted 23 degrees toward the feet. A small cone and a fine focus x-ray tube are necessary for proper detail. Exposure factors for an average adult are 66 kilovolts, 20 milliampères, three seconds and 28 inch target film distance. (Courtesy Drs. Sherwood Moore and Wendell G. Scott, Edward Mallinckrodt Institute of Radiology, St. Louis.)

The presence of salivary disturbance in the glossodynia group was not investigated until the return of saliva was described voluntarily by the tenth patient of that series. There have been twenty-two patients with glossodynia to date and among the last twelve, four have described constant dryness of the mouth. In these four the saliva has returned abundantly during the test treatment. Another, in the glossodynia group, with unbearable pain had excessive saliva which became normal after relief of pain. Another case not in the painful class had been diagnosed parotid tumor for twenty-three years. The gland remained enlarged and hard regularly and at intervals softened with discharge of a large amount of saliva into the mouth. Increase of vertical dimension of the jaw 3 mm on the

affected side in this case was followed by return of the gland to normal in four months. A direct parallel seems to exist between these clinical observations and some earlier experimental work on salivary secretion. Although the results of Heidenhain's experiments (1878), of stimulating the chorda tympani with weak induction shocks, showed that sympathetic impulses augment salivary secretion, other records showed an opposite effect. Czernak⁷ (1857) had shown that stimulation of the chorda tympani inhibited secretory activity of the submaxillary gland. Mislavsky and Smirnow (1893)⁸ "observed a similar inhibitory effect of sympathetic stimulation on the secretory activity of the parotid gland brought about by stimulation of the auriculotemporal nerve." When the factors of irritability of the gland cell as well as the effect of vasomotor change on the glands are recognized, one finds that the relationship of irritation of the chorda tympani and auriculotemporal nerves by the condyle to changes in salivary secretion is consistent.

For x-ray study, plates of the joints are taken with the mouth closed and open. Erosion of the head of the condyle on its anterior face, and to a less extent of the articular eminence, is the usual finding. Evidence is noted of fibrosis of capsule structures and of wide excursion of the condyle forward when the joint is greatly loosened. These x-ray examinations correspond with the pathologic studies of the joint by Dufourmentel,⁹ Axhausen,¹⁰ and Steinhardt.¹¹

A few of the patients with neuralgia complained of tinnitus of a mild grade, but the majority of the ear symptoms seem to be referable to simple overbite or overclosure of the jaw. Forty-two of the series presented ear symptoms. Thirty-two of them were edentulous or had natural teeth allowing a wide overbite. The majority of the forty-two ear cases presented headache in addition to deafness, tinnitus or dizziness. So it would seem that headache and the pain effects appear more common by a large majority than ear involvement.

The ear involvement was usually found to be mild and the result of compression of the eustachian tubes. Dizziness disappeared with the inflation of the eustachian tubes, and this was considered an important test in the diagnosis. Deductions as to the behavior of the tissues bordering the tube during overclosure of the jaw were made by experimental overclosure of the jaw of a soft tissue specimen. When this is done manually (to imitate similar overclosure in life) the tensor veli palatini muscle bordering the membranous anterior edge of the tube and the adjacent sphenomeniscus muscle are seen to wrinkle and crowd the eustachian tube, closing it firmly. During the act of swallowing, the tensor palatini muscle should be tensed and effect a temporary opening of the tube. This function cannot occur during overclosure, and the result is derangement of intratympanic pressure and dizziness. Continued production of the tube effects brings about a catarrhal or adhesive deafness exactly as produced by inflammation or pressure from the nasopharynx. The catarrhal deafness improves more or less after reposition of the jaw. The rate of improvement may be increased by inflation at intervals of the eustachian

tubes Follow up has been possible in only the earlier of this large group, but a tabulation of sixteen cases of dizziness showed twelve of the patients improved in hearing and relieved of dizziness

SUMMARY

Review of a large group of cases in which headache and ear symptoms were shown to be partially or altogether due to disturbed function of the mandibular joint shows this to be a common factor The description of pain and ear involvement are similar in every respect to some commonly known eye, sinus and ear disorders

Eighty-five cases fall into the pain group, and these include the ones with burning and sensory disturbance about the tongue and pharynx Four of these showed salivary disturbance, which may be directly traced to irritation of the chorda tympani and auriculotemporal nerves, these effects also were relieved

Thirty-five of the forty-two cases presented varying grades of catarrhal deafness, due either to compression from overclosure or to chronic nasal infection Four of the ear cases presented shortened bone conduction and were not improved by reposition of the jaw, these may be regarded either as eighth nerve deafness or as examples of microfractures of regions near the otic capsule interfering with transmission of sound waves to the inner ear, as observed by Guild¹¹ The dizziness is not typical of toxic labyrinthitis

Twenty-six of the series, or about 20 per cent of the cases, showed mild herpes of the buccal mucosa, angle of the mouth and external ear canal, all preceded by pain and improving with the disappearance of the other symptoms

The results of reposition of the jaws were generally good except in a few cases of malocclusion of natural teeth, presenting great difficulty However, it was noted that the cases showing the best results were corrected in several stages, slowly increasing the vertical dimension of the jaw This increase in distance is built into the molar district of the jaw and is not merely a problem of "opening the bite" Some failures to obtain a proper result have been traced to lack of understanding of this point and the anatomic problem involved by the dentist

722 Beaumont Building

ABSTRACT OF DISCUSSION

DR ROLAND M KLEMM, St Louis My interest in this subject was first aroused by a patient who presented herself with the following history She had pain in her face following the extraction of a molar on the right side She had visited three large clinics The first clinic advised the posterior section of the fifth nerve, the second clinic advised a section of the ninth nerve, the third clinic advised a superior cervical sympathectomy Her remark as she stated her story, was Just what shall I do? Fortunately none of these procedures were carried out She was referred to Dr Costen and was promptly relieved when proper treatment was instituted The neuralgia as described by Dr Costen is a definite clinical entity It is frequently associated with trigeminal neuralgia, because many of these patients had all their teeth extracted on the side of their pain and that is the cause of the associated neuralgia Even after the relief of the trigeminal neuralgia by section of the sensory root these patients continue to have the pain, owing to lack of proper support This is occasionally seen associated with glossopharyngeal neuralgia for the same reason It is important to give a differential diagnosis between a trigeminal glossopharyngeal neuralgia and a superior cervical

sympathetic pain A typical major trigeminal neuralgia is a definite clinical entity It is characterized by paroxysmal attacks of lightning-like pain in the distribution of the fifth nerve, more commonly in its maxillary and mandibular divisions, and very commonly associated with a point on the face that, when irritated or stroked, will precipitate an attack This is commonly spoken of as a trigger zone, usually the upper and lower lip at the angle of the mouth Trigeminal neuralgia is most commonly seen after the fifth decade, although it is occasionally seen in younger people It is unilateral as a rule, about 05 per cent are bilateral The point to remember is that it is in the distribution of the fifth cranial nerve Glossopharyngeal neuralgia, also a definite clinical entity that has been recognized for years, is a typical paroxysmal attack of pain in the distribution of the ninth cranial nerve In addition, one must take into consideration the differential diagnosis between this condition and supernumerary teeth, carcinoma of the lip, carcinoma of the alveolar process of the jaw and carcinoma of the anterior two thirds of the tongue Glossodynias, which have been rather baffling in the past, have responded very satisfactorily to this type of treatment The one patient that Dr Costen mentioned obtained immediate and permanent relief This type of neuralgia must be considered every time one deals with an individual who has not had proper support in the jaw after the molars have been removed, and only after the dental profession has been educated not to extract teeth in neuralgia will the incidence of this disease be cut down

DR WENDELL G SCOTT, St Louis With the patient reclining 23 degrees off the horizontal, the joint is roentgenographed on the under side The x-ray tube is centered one-half inch anterior to the external auditory canal and 1½ inches above it A small cone is used to give the utmost detail and contrast Both joints are always taken with mandible open and closed In Dr Costen's excellent study of the changes in this joint, three changes can be identified on the roentgenograms (1) the erosion of the anterior and superior aspect of the condyle involved, (2) a narrowing of the joint space with accompanying haziness and indistinctness of the bony outlines, which is indicative of arthritic changes, (3) the condyle on the involved side may move considerably farther forward on the eminence than does the normal side In studying films of the temporomandibular joints, the appearances of both joints must be carefully observed in the same manner that mastoid films are analyzed

DR SAM E ROBERTS Kansas City, Mo I have some slides to illustrate how this dental procedure is carried out I have been following Dr Costen's teachings nearly two years, and I am sure I have had at least fifty cases, both the pain syndrome and the ear syndrome One of my greatest difficulties has been getting the cooperation of the dentists I have tried to be ethical and return the patient to his own dentist, and there I made a mistake In one day there were three patients in my office who had had work done on their bite, and all of them had been improperly corrected In fact, they were no better, and their bite was not opened I have become unethical now I take them away from their dentist and send them to some one who I am sure knows something about this procedure As a consequence, I am getting satisfactory results I don't want to appear too enthusiastic, but I do feel that the work that Dr Costen has done has been one of the greatest advances in our specialty in many years He has claimed too little rather than too much

DR JAMES B COSTEN, St Louis I might say one thing regarding the relationship with the dentist When I examine the patient I tell him what I think the trouble is, and I establish it by having him wear those cork disks for fifteen minutes or two or three days I don't allow him to feel that his problem is solved and that I am through I have him back in two weeks, and again in a month, and try to analyze any changes in his pain especially if he is in the hands of a dentist who is disregarding, perhaps, the anatomic feature The traditional training of dentists is to open the bite What I try to impress on him is that, whether he opens the bite or not, the main thing to do is to increase the vertical dimension and allow the joint to pull down After that is done, in a week or so, the incisors come together and the joint has given way to allow for the correction These are the important points in getting results from a strange dentist if he is not thoroughly informed

CASE FINDING METHODS FOR THE DIAGNOSIS OF TUBERCULOSIS

J BURNS AMBERSON JR., MD

NEW YORK

The declining death rate from tuberculosis is one of the most impressive events in modern medical history. Yet the retreating force still holds a devastating outpost, so that it remains the most fatal disease of early adult life and causes physical disability, economic impairment and social disruption beyond accurate estimation. The pulmonary form and its direct complications are responsible for all except a small percentage of this. It seems paradoxical, therefore, to state the fact that pulmonary tuberculosis is one of the most readily diagnosable diseases and, in its early stage, one of the most curable.

In general, the percentage of tuberculosis cases diagnosed in their early stages has increased discouragingly little in comparison with the lowering death rate. The recent survey¹ by the Council on Medical Education and Hospitals of the American Medical Association reveals that only 13.1 per cent of 66,861 tuberculous patients were in the incipient or minimal stage of the disease when admitted for treatment to the hospitals and sanatoriums of this country. Surveys of various groups of the population of New York City in which I have participated more or less directly in the past five years demonstrate that there are a number of reasons for this situation, one of the most important being that at least 60 to 70 per cent of tuberculous people do not develop an awareness of ill health until the disease has entered the moderately advanced or far advanced stage. Even in a group of intelligent graduate nurses who are employed at Bellevue Hospital and may have medical examinations on request, we have found in a five years study that about two thirds of those who develop clinical tuberculosis have moderately advanced or worse lesions when the diagnosis is first made. The reason is that, in the early stages, subjective symptoms are lacking or misinterpreted as physiologic fatigue, nervousness or something equally innocent. It is difficult, by education of the lay public, to change this human tendency to ignore apparently small troubles. It is desirable therefore to seek for case finding methods that are effective for early diagnosis, practicable and not liable to arouse undue apprehensiveness in the population. That these conditions can be satisfied has been demonstrated by the five years study which we have made among student nurses at the Bellevue Hospital Training School for Nurses and by the work of many others. The methods are predicated on a recognition of certain prominent characteristics of behavior of tuberculosis in the community and in the individual.

TUBERCULOSIS AS A COMMUNITY DISEASE

In communities of people tuberculosis tends to pattern its behavior along well recognized lines. Young adults and adolescents are especially liable to attack. Young women are more vulnerable than young men, but the reverse holds true after the age of 25 or 30, and to a more striking degree. Color is a prominent element in the pattern especially in young people. Thus, in New York City the death rate is commonly five to ten times as high among young Negroes as among young

white persons.² Occupation is important since it usually is the determinant of living standards and on the expression of intelligence, very potent factors in the tuberculosis rate.³ Work in dusty atmospheres is a menace, especially if dust is that of siliceous rock. A thread which runs through the whole pattern is the opportunity for and intimacy of contact with the "open," sputum-positive case, usually in the household; this may have been recent or remote. Among 73,000 adult "contacts" examined in New York City, Chicago and London, Drolet² estimates that 8.2 per cent were found tuberculous.

THE EARLY LESION OF PULMONARY TUBERCULOSIS

Diverse as its variations may be, there is a certain constancy of behavior of tuberculosis in the person. The first lesion of clinical importance is most likely to develop in a young person, usually between 15 and 25 years of age. It appears usually in the upper half of one lung, as a patch of lobular pneumonic infiltration. At best, this may undergo almost complete absorption and scarring in a few months, entirely unknown to the patient; at worst, it may caseate, liquefy at its center and discharge its bacillus-laden content into the bronchial tubes, leading to contamination and infection of healthy parts of the lungs and the march of new lesions into advanced phthisis—all within a few weeks or a few months. Caseation is more constant than absorption, especially in the young, more especially in young females, and most especially in young colored females. Artificial as it may be, it is useful to set a dividing line between the early infiltrate and advanced cavernous phthisis, remembering that the former usually is the precursor of the latter. In distinction from the all too familiar picture of the latter, the early lesion does not give rise to cough or blood spitting, high fever or night sweats, but as a rule only to a mild toxemia which often expresses itself as easy fatigue, with loss of weight. Even these symptoms may not be recognized subjectively. There is, as yet, no softening or ulceration into the bronchus and therefore no sputum and no tubercle bacilli in discharges from the throat. Physical examination is entirely negative in about 75 per cent of the cases, and in most of the others the so-called finding is a patch of fine rales in an area so localized that it is almost covered by the bell of the stethoscope. The roentgenogram shows, with rare exceptions, a patch of soft mottling or clouding, which may be only a centimeter or so in diameter, its size often bellying its potentially dire significance.

Even after excavation of and bronchogenic extension from the original infiltration begins and proceeds—sometimes causing hemoptysis—the grippal, pneumonic or bronchitic character of the symptoms often deceive the patient, and sometimes the unwary physician also, particularly if the physical signs are scanty or lacking, if the need of x-ray examination is not recognized, or if reliance is placed on a single sputum examination.

If such alertness must be expected of the physician, the presence of the occasional patient with early tuberculosis who comes to the office or clinic with symptoms how are we to reach the much greater number who do not come before more advanced disease has developed. It is obvious that physical examination of large groups of people is not sufficiently reliable for the purpose. The most effective method is x-ray examination of the

3. Whitney, Jessamine S. Death Rates by Occupation, National Tuberculosis Association, 1934.

hest of groups of the population selected for their probable susceptibility to the disease. Such groups include young laborers in industry, factory girls, young mothers attending antepartum clinics, Negroes living in a low economic level, and high school and college students. In fact, a sizable community can determine, from mortality records, in what sections of the population tuberculosis has worked most of its havoc, and then survey those sections with the full expectation of finding nests of unrecognized disease.

The use of tuberculin testing before x-ray examination is a matter to be decided for each survey. In urban communities, where two thirds or more of the selected population groups are found to be tuberculin positive, it is usually simpler and more economical to proceed without this preliminary. In adolescents, especially, tuberculin testing is a good means of eliminating the majority who will not react and, therefore, not require x-ray examination.

Narrower searching concerns families and household groups principally. The death of an infant from tuberculous meningitis, for instance, means recent contact with an "open" case, and x-ray examination of the chest of each member of the household is likely to find this. Examination of "contacts" should always be carried out.

In ordinary practice, x-ray examination is made with the celluloid film. In large surveys the rapid paper film method has been found highly effective and economical. In certain groups, fluoroscopy of the chest as a part of the periodic physical examination approximates the roentgenographic method closely in efficiency.

The yield of case finding methods depends, of course, on the prevalence of tuberculosis in the community. Where the annual death rate from the disease is between 60 and 100 per hundred thousand of population, the yield of new cases usually is from 1.5 to 2 per cent of the number examined. In some groups, particularly in older people, it runs to 4 or 5 per cent, but in these the lesions are more often of a chronic fibroid and obsolete type. Of the lesions found, 70 per cent or more can be expected to be in the minimal stage according to the classification of the National Tuberculosis Association. In groups of young people, repetition of the examination annually will reveal a number of newly developed lesions in previously clear lungs, varying according to the rate of infection determined by the tuberculin test and the opportunity for reinfection. In a group of student nurses we have found an incidence of new lesions of about one per hundred annually. Yearly x-ray examination detects from 70 to 80 per cent of the cases in the minimal stage, and we have found that semiannual examination brings the percentage almost to 100. Not all of these lesions are serious nor do they all require treatment. Case finding, therefore, may accomplish little unless the yield is studied and sorted by physicians of experience, after proper clinical study. Remembering the potentialities of the early infiltration occurring in young people and causing few or no symptoms, the physician must have conviction as well as skill, since the prompt and proper treatment of such lesions is the most effective measure in combating tuberculosis. It is doubly effective, since it surpasses any other means of restoring a patient to lasting health and, simultaneously, is the best preventive of the development of advanced cavernous phthisis, which is the infection source of almost all subsequent tuberculosis in other people. It is apparent, therefore, that neither the case finding survey nor the skill and conviction of the

physician will be of avail unless facilities are provided for prompt and proper treatment. In most communities the sanatorium waiting list is a positive curse.

The cost of case finding is considerable, but trifling in comparison with the exactions of advanced tuberculosis in most communities.

SUMMARY

1 Pulmonary tuberculosis remains the first cause of death in young adults.

2 From 60 to 70 per cent of tuberculous people, even intelligent ones, are unaware of symptoms of serious disease until the pulmonary lesions are moderately or far advanced.

3 Most cases will not be diagnosed early except by case finding methods based on a familiarity with the characteristics of tuberculosis as a community disease as well as an individual lesion. Some of these characteristics are mentioned.

4 The simplest and most effective method of case finding consists of x-ray surveys of the chests of selected susceptible groups, in some instances with preliminary tuberculin testing.

5 In the yield of cases from such surveys, the proportion found in the earliest stage is 70 per cent or more.

6 If the cases found are skilfully studied and promptly and properly treated, when necessary, the accomplishment of actual cure of the disease and prevention of spread of the infection to others exceeds that of any other known methods.

Bellevue Hospital

ABSTRACT OF DISCUSSION

DR. GEORGE H. HOWE, Kansas City, Mo. The difficulties with the procedure are twofold. Most physicians are loath to take on this new work, and secondly there is lacking in the community physicians willing to take the leadership in the unpopular work of carrying on surveys and preventing the disease rather than curing it. Yet it rests with the medical profession to decide what is to be done. In those communities in which the medical profession has studied the matter there seems to be a gradual recognition that something should be done and that it is up to them to do it. But if we do not take that attitude we should not be displeased with the general public if it takes up this work of preventive medicine. One of the chief difficulties in discovering early cases has been the difficulty in recognizing early lesions. And it is only by the recognition of the early processes that we can hope to secure a real advance in this campaign. It seems to me that in the Middle West we would have to make an approach different from that suggested by Dr. Ambersson. It will be easier for us to enter the public schools and take the pupils in groups on which to carry on our surveys. And I believe that it would be wiser if we went below the adolescent age and examined the students in the elementary grades, not so much with the view of finding the disease full blown as by using the tuberculin test to find familial infections, foci of infection, the carriers, and the fibroid types of disease hidden through former wrong diagnosis. I should like to see the feeling general among the medical profession that tuberculin testing should be done in the preschool age or in the first year of the elementary grades, in order to find foci of infection. Surveys in high schools should be done with the aim of recognizing the individuals about to become sick. The next question was concerned with what to do with children who show positive tuberculin tests. Most of them do not need sanatorium treatment, but they do need very close supervision. Another point is to have x-ray work that is above reproach. Much of what I have seen has been questionable, and I believe that it will be necessary to ask for better machines—machines that will make an exposure through a youngster's chest in a tenth to a twentieth of a second—and to have interpretations of films by men who understand the beginning lesion rather than cavitation and fatal or far advanced lesions.

DR. WILLIAM DEVITT, Allenwood, Pa. We who live in institutions and work with tuberculosis all the time are impressed with the statement Dr. Amberson made that only 13 per cent of the cases that come under our observation are incipient. I know of nothing easier to cure than early tuberculosis and of nothing harder to cure than far advanced tuberculosis, the kind that all institutions get. I believe thoroughly that we shall never control tuberculosis until we have brought that to the attention of the family physician. He is the first to see the case, whether it is minimal, early or far advanced. Until we wake him up to that possibility, we shall never do much to stamp out tuberculosis. It has been shown that one out of forty-six school teachers has an active, positive tuberculosis. It has been shown that there are 18,000 school teachers in the United States who have positive tuberculosis. If that is true, it behooves us to do something about it. Dr. Myers of Michigan has done a great deal of work in that direction, until the state of Michigan, because of Dr. Myers' efforts, began to demand that every school teacher have a clear bill of health either by a tuberculin test or by competent x-ray examination. I do not know how to bring about this state of affairs. It certainly is not a federal or national concern. It must come from the local boards and from them to the local states. It is a problem for each state. If school teachers are compelled to undergo an examination they will be helped because they can be cured. We always have between five and nine school teachers. Nobody today knows the solution of the problem of tuberculosis. Miss Whitney has said that it is going to be more difficult from now on to lower the death rate than it has been for all these years, because we have done the obvious and now we have to go out and find the hard, difficult things to do.

DR. SAM H. SNIDER, Kansas City, Mo. In tuberculosis we look for the woman who infected the child. It may be a mother, it may be a teacher, it may be a grandmother. In a case of tuberculosis in a child whose father, the mother, the cook and the chauffeur showed no signs of tuberculosis on examination, the grandmother apparently was the source of infection since she had a moderately advanced tuberculosis. Dr. Pinner and Dr. Amberson have stated clearly the epidemiology and the pathology of early tuberculosis. I like to use the term "childhood type tuberculosis," not "childhood tuberculosis," because childhood type tuberculosis is not peculiar to childhood but may be seen in adult life. It is seen in people past 40. The progression from the childhood type to the adult type of tuberculosis may be very rapid. What yesterday was a childhood type of tuberculosis, with only a caseated gland in the hilus tomorrow may be a far advanced tuberculosis. Let us therefore not forget that any child with a childhood type of tuberculosis, particularly as he is approaching the adult stage of life, may within a month or two become a menace to the community. We should reexamine the children with the childhood type of tuberculosis. I like to examine them with the fluoroscope not less often than every two or three months to determine if there is any progression of the lesion and if there is any suspicion I like to use the x-ray plate to determine further the progression. Tuberculin tests are made for the purpose of determining who shall have x-ray plates. The x-ray plate will determine the degree of advancement. If we can apply pneumothorax therapy to the adult case fairly early as soon as cavitation appears we shall be very much more likely to suppress the infection before that individual has spread his infection to a large number in the community.

DR. H. I. SPECTOR, St. Louis. In a study of statistics of the tuberculosis mortality in St. Louis it was found that 50 per cent of the cases were reported after death of the patient or a month before death. A questionnaire was sent to the physicians in St. Louis asking them to state the reasons for late reporting. Some 25 per cent of the physicians frankly admitted that they were unable to recognize the disease in its early stages. Others stated that in many instances in which the diagnosis was in doubt they would suggest to the patient the necessity of a roentgenogram but the patient could not afford to pay for it. The advice to have sputum examined was not always followed. The patients likewise failed to return for observation. These are practical points that come up in the control of tuberculosis. Many physicians stated that the patients came to the physician in a late stage of the disease, when the damage has already been done. Those of us charged with

the responsibility of controlling tuberculosis have these practical problems to face. In our own city, we felt that, as physicians admitted that they were unable to diagnose and recognize early tuberculosis, something had to be done about it. We have for this reason instituted courses on tuberculosis. We offer annual courses to physicians, stressing practical points not immunology or pathology. Because of the fact that tuberculosis in the early stage does not always manifest itself in signs, we are teaching them other methods of diagnosis. I think we have been fairly successful in getting the cooperation of the physicians. We are going to conduct our fifth annual session this coming fall. How to get the patient to come to the doctor early in the disease is always a problem. Through the radio and the press we are advocating and urging periodic health examinations. It seems to me that unless we attack the problem from these two angles, we are going to fail in recognizing the early cases.

DR. J. BURNS AMBERSON JR., New York. In the past five years during which we have used such case finding methods among student nurses in the Bellevue Hospital Training School we have regarded these small newly developed lobular perimonic lesions seriously and have given the cases prompt and rigid treatment. In the group so treated there has not been a single death from tuberculosis and not a single case has gone on to advanced disease. Practically all these girls who have finished treatment are now back at work and thus far have had no further trouble from their tuberculosis.

PRIMARY MALIGNANT DISEASE OF THE TRACHEOBRONCHIAL TREE

REPORT OF 140 CASES

PORTER P. VINSON, M.D.

ROCHESTER, MINN.

One of the interesting developments of the past decade has been the marked increase in the incidence of primary malignant disease of the tracheobronchial tree. Prior to 1925, primary malignant growths in the air passages were considered rare, at present, however they are encountered as frequently as pulmonary abscesses.

It is true that certain types of malignant growths arising primarily in other organs may metastasize to the lungs and ulcerate through the bronchial wall, producing signs and symptoms that are identical with those occasioned by primary bronchial growths,¹ in most instances, however, the differentiation of primary and secondary neoplasms in the lung is not difficult. Metastatic nodules in the lungs, even though they may be large and numerous, rarely produce signs or symptoms of pulmonary disease unless they involve the pleural surfaces and cause pain or effusion into the pleural space. When secondary growths are situated in the parenchyma of the lung, they may be unsuspected until a roentgenogram of the thorax reveals their presence. In contradistinction to metastatic nodules in the lung, a small growth arising in a bronchus may soon reduce the lumen of the tube and interfere with drainage to such an extent that suppurative processes may mask the underlying disease.

The chief factor in the more frequent antemortem recognition of primary malignant growths in the air passages has been the more general employment of

bronchoscopy in the diagnosis and treatment of chronic pulmonary diseases and the removal of tissue for microscopic examination

Doubt as to the accuracy of pathologic reports in these cases has recently been expressed, especially by Kernan² and also by Kramer,³ who felt that many of the growths found in the bronchi are benign and should be classified as adenomas or carcinoid tumors. They contended that, although the tumors may resemble carcinomas, they do not exhibit evidence of mitosis, are more frequently encountered among women, produce symptoms because of mechanical interference with bronchial drainage, never produce metastatic lesions, are readily removed by diathermy but are insensitive to irradiation, and may be diagnosed accurately from their gross appearance at bronchoscopic examination. While it is not my purpose in this report to attempt to settle this controversy, I can state that from the pathologic, clinical, roentgenographic and bronchoscopic observations it is felt that the lesions in the cases presented in this paper represent true malignant tumors. While some may have been benign, it was not possible to distinguish them in any way from malignant tumors.

From May 1925 to January 1931, at the Mayo Clinic, a diagnosis of primary malignant disease of the trachea or bronchi was made from microscopic study of tissue removed at bronchoscopic examination⁴ in seventy-one cases. From January 1931 to June 1935 a similar diagnosis was made in sixty-nine additional cases. The purpose of this report is to analyze all these cases and the results obtained from the various types of treatment employed. One hundred and ten of the patients were men, thirty were women. Five patients were from 20 to 29 years of age, sixteen from 30 to 39 years, thirty-two from 40 to 49 years, fifty-one from 50 to 59 years, and thirty-four from 60 to 69 years, one patient was 72 and another 75 years of age.

Many factors have been mentioned as influencing the development of carcinoma in the lung, one of which is tuberculosis. In the present series tuberculous infection in the lung was present in only two cases. It does not seem likely that tuberculosis is an etiologic factor, as the increase in malignant lesions of the lung has come at a time when tuberculous infections have shown a decided decline.

Other respiratory infections had been present in sixty-eight cases, but there was little evidence to establish an etiologic relationship as most of these infections were mild and were not associated with the development of symptoms leading to a diagnosis of pulmonary carcinoma. However, there were a few cases in which malignant disease had developed in the respiratory tract of patients who had suffered from chronic bronchiectasis for many years. Seventy of the patients were smokers, which certainly was not a noteworthy finding. There was a family history of carcinoma in nineteen.

Practically all chronic pulmonary diseases have similar symptoms and it is futile to attempt to distinguish one from the other on the clinical history alone. One of the most frequent symptoms of pulmonary disease is cough, and yet it is an interesting feature of pulmonary carcinoma that an advanced lesion may exist

with evidence of metastasis and stenosis of a bronchus without cough being present. This was true in ten of the cases. Three patients had not noted any pulmonary symptoms. Dyspnea was a prominent symptom and was present in ninety-nine cases. Pain in the thorax was noted by ninety-three patients, and in many instances it was a very disturbing symptom. Sputum was present in 100 cases, and hemorrhage or blood-stained sputum had been noted in eighty-four. One hundred and twenty-one of the patients had lost weight, and this was usually associated with more than a corresponding loss in strength.

Stridor, which was present in thirty-five cases, is usually interpreted as being produced by an obstructing lesion proximal to the bifurcation of the trachea, in the majority of these cases, however, the lesion was situated well beyond the carina. In one case definite stridor was produced by a lesion that obstructed a bronchus to the lower lobe of the lung. Any lesion producing bronchial occlusion interferes to a greater or less degree with drainage from that area of the lung distal to the obstruction and infection invariably ensues. Evidence of sepsis occurred in many of the cases in the series. Fever was present in sixty-two cases, sixteen patients had had chills, and fifty-five had leukocytes numbering more than 10,000 per cubic millimeter. Ten patients had clubbing of the fingers. Eighteen had had an effusion into the pleural space.

The most significant physical sign was evidence of bronchial obstruction as revealed by distant breath sounds, which was noted in 113 cases. This finding is noted rarely in other pulmonary diseases without involvement of the pleura and when it is observed without corresponding impairment of the percussion note over the area involved, carcinoma should be suspected at once. In some cases breath sounds were markedly reduced or absent when on bronchoscopic examination the bronchial lumen did not appear to be greatly narrowed. This is in striking contrast to the absence of physical signs in cases of inflammatory lesions of the lung, especially in cases of pulmonary disease in which the lumen of the bronchus is greatly reduced in size.

Distant metastasis may present the first evidence of primary bronchial carcinoma. This has been true particularly in cases in which secondary lesions have occurred in the brain. In a few instances glandular metastatic lesions were not demonstrated, although metastatic nodules in the opposite lung were revealed on roentgenographic examination.

Twenty-eight of the patients in the series had definite metastatic lesions, in one case metastasis was questionable. Seven patients were hoarse as a result of involvement of the nerve supply to a vocal cord, in five of these cases metastatic masses were not demonstrable.

Roentgenographic examination revealed the presence of a lesion in 136 cases. In one case in which the examination was considered negative the tumor was situated in the trachea, in three cases in which the lesion was situated in the lumen of a bronchus, however, examination failed to reveal the presence of disease. In some cases the roentgenologic appearance of bronchial carcinoma is quite characteristic, but in the majority of cases it is impossible to distinguish malignant from benign lesions. In four cases the lesions were situated in the trachea, in the remainder they were bronchial in origin. In eighty-seven cases lesions were on the right side, and these were distributed as follows: thirty-one in the main bronchus, forty-three in the bronchus to the

lower lobe four in that to the middle lobe and nine in that to the upper lobe. Forty-eight of the lesions were on the left side, twenty-seven of these were in the main bronchus, fifteen in the bronchus to the lower lobe, and six in the bronchus to the upper lobe.

In one case both main bronchi were obstructed by the tumor and it was impossible to determine the origin of the growth. In this case death occurred immediately after withdrawal of the bronchoscope and was evidently the result of bilateral bronchial occlusion. Symptoms of respiratory limitation in this case were not pronounced until immediately before examination was begun, and they were erroneously attributed to a nervous reaction associated with instrumentation. This was the only fatality that was related in any way to examination.

According to the method of grading advocated by Broders, carcinoma of the bronchus represents a high degree of malignancy. Seventy-six of the lesions were squamous cell epitheliomas, forty-two of these were graded 4, thirty were graded 3, three were graded 2, and one could not be graded satisfactorily because the tissue was insufficient in amount. In fifty-nine cases the lesion was an adenocarcinoma, twenty of these were graded 4, twenty-seven were graded 3, six were graded 2, and six were graded 1. Undifferentiated carcinoma of grade 4 was present in two cases and of grade 3 in one case. One lesion was not graded and one was thought to be lymphosarcoma.

Although there was no difference in the pathologic appearance of tissue removed from the seventy-one patients observed in the period from May 1925 to January 1931 and from the sixty-nine who were examined from January 1931 to June 1935, there was nevertheless a striking difference in the clinical course in these two groups. In the first group metastasis had occurred in ten cases, whereas in the second group it occurred in eighteen. In the first group pleural effusion was present in six cases and in the second group in twelve. In the first group eight patients survived for as long as four years following high voltage roentgen therapy, and six of these were living at the time of writing, from four to seven and a half years after treatment.⁵ In the second group four patients are living and are in satisfactory condition ten, eleven (two cases) and thirty months following irradiation or local destruction of the tumor by surgical diathermy, a fifth patient in this group is living but is in failing health one year after irradiation. All patients in each group who did not receive treatment are dead, in the first group thirty patients who were not treated lived an average of six months after examination at the clinic in the second group twenty-six who were not treated lived little more than an average of four months. Excluding those patients in the first group who at the moment of writing were still living the duration of life of the thirty-five patients who received treatment was more than twelve months, the duration of life of the thirty-eight patients in the second group who received treatment on the other hand was five and a half months. It would appear from these data that neoplastic disease of the tracheobronchial tree is not only becoming more frequent but is exhibiting increasingly malignant characteristics.

Although it seems unwise to draw too sweeping conclusions as to prognosis from study of small groups of cases representing different types or lesions neverthe-

less from my experience better results have been obtained from treating patients with adenocarcinoma than those with lesions of the squamous cell variety. Nine of the eleven patients who are living had lesions of the adenocarcinomatous type. Four of them are women, the remaining five, men. Of the two patients with squamous cell tumors, one is the man who is failing rather rapidly a year after treatment and the other is a woman who was well four years after treatment.

Numerous investigators have reported gratifying results following surgical removal of malignant growths from the lung, but, as equally good or better results can also be obtained by a combination of radiotherapy and surgical diathermy in the treatment of an adenocarcinomatous type of lesion, it would seem proper at present to restrict radical operation to the squamous cell type of tumor.

ABSTRACT OF DISCUSSION

DR. JOHN DEVEREUX KERNAN, New York. Up to 1933 there had been in the Presbyterian Hospital in New York sixty-six cases of carcinoma of the lung, in the past three years there have been sixty-five cases. This reports a material nearly as large as that of Dr. Vinson. At the Lenox Hill Hospital in New York between 1923 and 1933 there have been twenty-eight additional cases. All the large hospitals report the same increase, in spite of the fact that in many large hospitals the bronchoscope is not yet in frequent use. The etiology is just as obscure as in carcinomas anywhere else in the body. There are undoubtedly cases of a primary tumor of the bronchus which closely resemble carcinoma and are reported as such by the pathologist. Nevertheless, their history and course are non-malignant. They begin early in life and persist for many years without metastases. Their symptoms are purely the local ones of the obstruction of a main bronchus. Local treatment by diathermy or even by removal by forceps will cure them. Surely these are not what are ordinarily thought of as cancers. It is important to recognize them, as they will be reported by the pathologists as carcinomas and the most radical treatment, such as lobectomy and pneumonectomy, may be proposed. It is surprising that, in spite of his broad clinical experience, Dr. Vinson has not yet encountered tumors which, for lack of a better name, are called adenoma. Dr. Vinson makes the important point that all chronic pulmonary diseases have similar symptoms. Neither the history, the physical examination nor the x-ray appearances are characteristic. Only by bronchoscopic examination and the removal of a specimen for biopsy can the diagnosis be made with certainty. The next most valuable means for making the diagnosis is the x-ray examination, which in Dr. Vinson's series revealed the lesion in 136 out of 140 cases. Dr. Vinson approves only of x-ray treatment and has made little mention of the various surgical attacks that are now proposed. I believe that successful lobectomies and pneumonectomies have been reported by a number of authors. It has not been my good fortune to see one of these successful cases. I should like to ask Dr. Vinson whether he has had any experience with surgical procedure and whether he has seen any that even promised hope. The experience of Bellevue Hospital has been a complete failure as far as surgical measures are concerned. The results of x-ray therapy have not been encouraging. In the twelve years from 1922 to 1934 seventy-two males and thirty-two females with carcinoma of the lung were treated by x-ray therapy at the Presbyterian Hospital. Only twenty-one of these cases received a satisfactory dose. The others had been treated in earlier years with smaller dosage and in some cases lower voltages. Four of the twenty-one patients survived between fifteen and twenty-eight months.

DR. EDWARD H. SKINNER, Kansas City, Mo. The following procedures may be used in the treatment of a carcinoma of the lung: (1) a lobectomy, (2) a pneumonectomy, (3) the placing of a radium container with radium element opposing the lesion, (4) the use of radon implants, (5) the use of surgical procedure of lobectomy plus radon, and (6) the matter of high voltage roentgen therapy. This discussion is from the angle of what might be hoped for with high voltage roentgen therapy.

⁵ Vinson, P. P. and Leddy, E. T. The Roentgen Treatment of Primary Malignant Disease of the Tracheobronchial Tree. *Ann. Otol., Rhin. & Laryng.* 45: 129-126 (Dec.) 1932.

when the surgeon agrees that lobectomy or pneumonectomy is not possible. Gamma irradiation, when one is treating a malignant growth in any circular organ, provides the possibility of producing a stenosis of that organ in the process of healing. Therefore I am inclined to agree with Dr Kernan when he says that some of the cases treated with high voltage therapy have not been benefited but their condition made worse. Undoubtedly the same result may take place in the case that has not been treated with x-ray therapy. It is my observation in the career of these cases that the disease itself may produce the blocking, with the infection developing in the particular area behind the stenosis. One must be careful in attempting to apply a lethal dose of x-ray therapy to any large area, and therefore if any one is proposing to use high voltage therapy on these lesions, may I suggest that he carefully localize the lesion. With the fluoroscope a lead circle is placed on the posterior wall of the patient and another lead circle on the anterior chest wall. The lesion is lined up directly between these two circles with a straight beam of the x-rays. The x-ray therapy should be introduced through a very small portal, not more than a 5 cm port, possibly smaller. This must be focused most exactly and the x-ray film with the record of the fluoroscopic examination must be at hand so that one can actually center on the particular portion of that lung. If one does use a large port of high voltage therapy on lung tissue, one should be cognizant of what has happened in the treatment of mammary carcinoma. I have produced a pleuritis, a pneumonitis, with consequent fibrosis. I have produced such a thickening of the pleura as to obliterate the space of a lobe. Therefore, all high voltage roentgen therapy must be done through very small portals. This will give another advantage, that of introducing a far larger amount of gamma radiation to that particular area by cross-fire. Large skin portals sacrifice avenues of cross-fire. It is folly to attempt to apply x-ray therapy anteriorly and posteriorly to a chest presenting a malignant growth. It is high time that the beam be focused directly and intimately on the lesion which has been properly localized by means at hand.

DR. MILLARD F. ARBUCKLE, St. Louis. Malignant disease of the lung probably is increasing. Abscess usually is present and often obscures the diagnosis. Improved methods of study have increased the number of positive diagnoses. Except by direct extension from contiguous growth, as in cancer of the esophagus, invasion of the bronchial wall from a metastatic lesion is unusual, but I have seen the biopsy specimen from a case in which a melanoma of the cheek metastasized to the bronchial mucosa. In about 33 per cent of our autopsies there has been involvement of the adrenal glands. Metastatic brain lesion occasionally is the first sign of primary endobronchial carcinoma. Prognosis and treatment based on microscopic classification alone is not satisfactory. Tuttle and Womack showed that a well differentiated cancer arising from a small bronchiole may resemble a very poorly differentiated cancer arising from a major bronchus. It follows that most well differentiated cancers arise in the major bronchi, while those of the poorly differentiated variety arise in the minor bronchi. Analysis of sixty cases selected from a group of 150 showed that carcinoma originating in the major tubes permitted a much longer duration of life than those originating in the smaller tubes and in the periphery of the lung. Some patients with treatment and some without in cases of tumors originating in the major bronchus lived an average of 26.3 months from onset of the symptoms to death. Two patients lived sixty months and one fifty-four months, whereas those with tumor in the parenchyma lived on an average only 7.3 months from onset of the symptoms to death. Early in its course bronchiogenic carcinoma invades the bronchial wall though the bronchial wall probably forms a temporary barrier between the cancer and the regional lymph nodes. This barrier has already been passed in most cases when the patient is first examined. The curability of bronchiogenic carcinoma like that of cancer elsewhere in the body, depends on its extent and on the possibility of its being completely removed or destroyed. Because of its distribution the hope of cure of endobronchial carcinoma by the local use of cautery or radon seeds is not well founded, but palliation may be possible. In benign tumors I have no doubt that cure may occasionally be obtained by the use of diathermy

or cautery or by irradiation. This would apply especially to polypoid, adenomatous lesions projecting into the bronchial lumen with very little infiltration of its wall.

DR. EDWIN N. BROYLES, Baltimore. For the last twenty-five years, bronchoscopy has gone ahead by leaps and bounds, owing to the work of Killian in Germany and of Dr. Jackson and his co-workers in Philadelphia. For the last three years thoracic surgery has started upward, and I believe that the solution for the treatment of large tumors and carcinomas is going to lie in the field of thoracic surgery. I believe that surgical treatment is the correct treatment for the removal of these large tumors. When looking down through the bronchoscope, one has no idea of the size of the growth; one merely sees the top when it completely occludes the bronchus. These tumors occur in young adults, who, I believe, can stand the operation fairly well when there is no infection.

DR. PORTER P. VINSON, Rochester, Minn. The physicians who have kindly discussed my paper have brought up some interesting questions with regard to carcinoma of the bronchus. One of the difficulties about determining whether radical operation should be employed in these cases is the fact that the pathologists have not settled the type of tumor in the bronchus. At present I should hesitate to advise surgery in the cases classified as adenocarcinomas, because, as Dr. Kernohan has pointed out, these tumors, whether they are adenomas or adenocarcinomas, respond to diathermy and to irradiation. In the majority of instances the tumors are located near the bifurcation of the trachea, and many of them have metastases or pleural effusion at the time of examination. Thus, of course, reduces the accessible and favorable cases to a very small number. I should hesitate to attempt removal of one of these tumors with forceps. Many of them are quite vascular and in one of my recent cases, a rather severe hemorrhage followed coagulation with the diathermy needle.

THE PRESENT STATUS OF OXYTOCICS IN OBSTETRICS

M. EDWARD DAVIS, MD
FRED L. ADAIR, MD
AND
SARAH PEARL, MD
CHICAGO

The rapid strides that obstetrics has made in the present century has detracted little from the universal popularity that the oxytocic drugs have enjoyed since their introduction into medicine. New drugs and many derivatives of the older drugs have been introduced from time to time, and some have added confusion to the therapeutic armamentarium of the obstetrician. Clinical impressions on the value of many of these oxytocics have had to give way to sounder methods of investigation and evaluation. It is thus not surprising to find that many of the therapeutic claims for drugs used in ancient eras have not withstood the test of time and progress.

The first authentic oxytocic drug introduced into medicine was ergot. The medicinal properties of this fungus, which attacks rye, the consumption of which resulted in widespread epidemics of "ergotism" leaving mutilation and death in its wake, was known to European midwives. However, it remained for John Stearns¹ of Stratoga, N. Y., to introduce its use in obstetrics in 1807. Many other medicinal herbs and drugs of various kinds were used by earlier peoples all over the world for their oxytocic properties in labor and the puerperium but more often as abortifacients. Although most of these therapeutic agents have been

¹ Stearns, John. New York M. Repository 11: 1807.

lost in the limbo of time, ergot still serves mankind. Recent investigations have resulted in a new active principle derived from this drug, which is probably responsible for most of its desirable oxytocic activity, so that much of this paper will be concerned with this new agent.

The crude drug contains many constituents, some of which are peculiar to ergot, others not, some of which exhibit oxytocic activity, others being relatively inert

Fig 1—A kymographic tracing of uterine motility following the oral administration of 3 mg of ergotamine. No uterine contractions occurred for nearly an hour, although the uterus promptly responded following the administration of 0.2 mg of ergonovine orally. B a second record in which no uterine response followed the oral administration of 3 mg of ergotamine tartrate. The above curves demonstrate that the desirable effect of ergot does not reside in its previously described alkaloids.

Medicinal preparations of ergot were in common use in obstetrics before any of the now known constituents were isolated and identified. Thus the earliest decoction prepared by Stearns² consisted of one-half drachm (2 Gm) of powdered ergot in one-half pint (236 cc) of water boiled and given to the patient in three doses at twenty minute intervals. This preparation was crude and unstable, and of questionable potency and dosage. The efficacy and value of the drug soon led to its official recognition by the pharmacopoeias of this and other countries. The alcoholic extract became the U S P preparation in which a 49 per cent alcoholic solution is used. The aqueous extract became the official B P preparation, in which water is used in the extraction of the crude drug, and alcohol is added as a preservative.

Various pharmacologic methods of biologic assay are used to assure the potency and uniformity of these official preparations. There are three methods of assay of ergot for potency in common use today. The cock's comb method has been given official recognition in the United States Pharmacopoeia. This method makes use of the phenomenon of ergotism. A standard fluid-extract of ergot when injected into the breast muscle of a cock, in a dose not exceeding 0.5 cc per kilogram of body weight, i. e., about 1 cc per fowl, will show marked bluing of the cock's comb. These fowl are all standardized. The Broom-Clark method of biologic assay has become official in the British Pharmacopoeia. Here the pharmacologic antagonism of ergot and epinephrine is utilized. When isolated uterine strips from rabbits are treated with epinephrine the motor action of this drug is abolished by a standard ergot preparation.

Tuoret³ in 1875 isolated ergotamine from crude ergot. Although this alkaloid proved to have no oxytocic properties, ergotamine isolated by Barger and Carr in 1906 was found to contain some activity. Stoll⁴ in 1918 isolated and described an inactive alkaloid from certain strains of ergot which he called ergotamine and its active isomer ergotamine. In recent years two other

alkaloids, sensibamine and ergoclavine, have been reported. Little work has been done on the latter drugs. Thus, of the four well known alkaloids present in ergot at least two exhibit oxytocic properties.

With the advent of the pure alkaloids, some of these were substituted therapeutically for the aqueous and alcoholic extracts. Ergotamine and ergotamine, when studied by the present methods of investigation on the human uterus, are found to have a very unreliable action when given by mouth in several times their therapeutic dose (fig 1). When any oxytocic activity is manifested, it is delayed and irregular in its exhibition. Parenteral administration evokes a variable response in large doses, coming on after a considerable length of time. Thus these newer experimental data definitely prove that the oxytocic activity residing in the crude extract is not due in a great measure to these known alkaloids.

Until Moir⁵ began his investigations on the aqueous extract (B P) it was generally assumed that all the desirable activity of ergot in obstetrics was due to the known alkaloids in the preparation. Indeed, Barger,⁶ in his monograph on ergot and ergotism, states that the quantity of the total alkaloids is a measure of its physiologic activity. Moir⁵ studied the official B P aqueous solution and found that it was an active oxytocic preparation even though it was low in alkaloidal content. He further showed that the presence of ergotamine, ergotamine and histamine were not in themselves sufficiently active to account for the entire oxytocic activity of ergot preparations. These experi-

Fig 2—Appearance of crystals of ergonovine maleate

ments were confirmed by us and by Koff,⁷ working independently. All these experiments crystallized the idea that crude ergot still contained an unknown substance, soluble in water and unlike the known alkaloids which was responsible for most of the desirable activity present in the drug.

ERGONOVINE

Following a long series of investigations, Davis, Adair, Rogers Kharasch and Legault⁸ announced that on Dec 12, 1934, they had succeeded in isolating and testing clinically a pure, crystalline base from the crude extract which further study proved to contain most of the desirable oxytocic activity. The name "ergotocin" was given to this new active principle. Independent studies carried on in other laboratories led to similar discoveries.⁹ These independent groups assigned different names to this new ergot base, which subsequent chemical comparative analysis proved to be the same. To obviate further confusion, the Council on Pharmacy and Chemistry of the American Medical Association has renamed this new substance ergonovine,¹⁰ although in all our previous communications the new oxytocic principle was called ergotocin. In all our future communications we will refer to this new substance by the name approved by the Council of the American Medical Association.

The Empirical Formula and Chemical Characteristics—Ergonovine comes under the broad definition of an alkaloid. However, it differs chemically from the previously isolated alkaloids of ergot. Unlike the other alkaloids in ergot, ergonovine is not precipitated by Meyers' reagent in a dilution higher than 1:6,000, while the other alkaloids are precipitated by that reagent in dilutions as high as 1:2,000,000.

It is a colorless, crystalline material appreciably soluble in water, imparting to the latter a weak alkaline reaction. It may be crystallized in long, fine, needle-shaped forms from such solvents as chloroform, benzene and trichloroethylene (fig 2).

The empirical formula for ergonovine is $C_{19}H_{27}N_3O_2$. The formula previously reported¹¹ for ergotocin, $C_{21}H_{27}N_3O_3$, was obtained from analyses on samples dried in vacuo at a temperature of 40°C. This low temperature was selected because we found that prolonged heating at a higher temperature (100 degrees) inactivates the material. Our samples for analyses contained a molecule of alcohol of crystallization, so that when a higher temperature is employed (76 degrees) in drying the samples our analyses are in agreement with those recently reported by Dudley and Stoll.¹² These data are in complete agreement with all our reported results, i.e., the molecular weight and the presence of three active hydrogen atoms in the ergonovine molecule. It is clear, however, that one of these active hydrogens is in the alcohol molecule and the other two active hydrogens are part of the ergonovine molecule.

The degradation of ergonovine in our laboratories has yielded lysergic acid and a base which at the time was the object of further study.¹³ In the meantime Jacobs and Craig have identified this basic hydrogen product as propanolamine, and our independent study has led to the same result. From these observations

it is quite obvious that ergonovine is a much simpler molecule than ergotamine or ergotoxine. All these substances, however, have a similar structural skeleton (lysergic acid) and our studies of the absorption spectrums corroborate that view.

Ergonovine is a rather unstable substance, and when solutions of the salts are heated in sealed tubes for any length of time the material decomposes, as indicated by darkening of the solution and loss of potency. When kept at ordinary temperatures, solutions of some salts of ergonovine are relatively stable. An investigation is under way in our laboratories at the present time to determine the rate of decomposition of solutions of ergonovine salts and the various factors that influence this decomposition. It should be noted here that, while ergonovine can be assayed by the Smith colorimetric method,¹⁴ it cannot be analyzed by the same procedure employed in the assays of ergotoxin and ergotamine. The chief difference is in the fact that ergonovine when in solution cannot be extracted from water by ether. The method of Smith should be changed to include chloroform as the solvent of extraction. With that modification, ergonovine can be assayed quite readily.

Fig 3—Kymographic tracings of uterine motility showing the action of ergonovine on postpartum uteri by (A) intravenous, (B) oral and (C) intramuscular administration. Note the immediate response of the drug following intravenous administration and the delay of only six to eight minutes following its oral and intramuscular use. The tetany is well maintained and as it subsides increasingly vigorous contractions occur. The activity of the drug lasts two hours or longer.

by following the procedure suggested by Smith. For quantitative assay it is also essential to extract three or four times with chloroform, to make sure that the water solution is thoroughly saturated with salts and that the pH is not lower than 6.8 and not higher than 8.2.

Pharmacology—The new ergot alkaloid may be primarily assayed by the U S P cock's comb method and by the isolated uterine response. It cannot be assayed by the Broom-Clark method.¹⁵ Unlike ergotoxine and ergotamine, it has little inhibitory action on epinephrine. The maleate salt of ergonovine shows little toxicity. The minimum lethal dose when given intravenously is 250 mg per kilogram in mice and 80 mg per kilogram in guinea-pigs. That this new ergot principle has a stimulating action on the sympathetics is evidenced by the fact that it causes mydriasis on instillation into the rabbit's eye, constriction of the frog's limb vessels, and relaxation of the rabbit's small

intestine. The latter effect can be abolished by the previous application of ergotamine. The new ergot principle has a demonstrable pressor action on pithed cats but a depressor action in anesthetized animals. In large doses it suppresses respiration. In rats it increases the metabolic rate when injected intravenously in appropriate doses.

Ergonovine is the only alkaloid of ergot which is effective by oral administration in small doses. When administered in doses of from 0.2 to 0.4 mg by mouth it causes a typical ergot response in six or eight minutes. The uterus develops tonic and following the initial tetany, which lasts five or six minutes, uterine motility is established which becomes more vigorous in character as the uterine tone diminishes. Good uterine motility continues for at least two hours and often longer, so that frequent administration of the drug is not necessary. Intravenous administration in doses of 0.2 mg produces an immediate response, particularly marked by the high degree of tone, which is of great importance in its therapeutic application (fig 3).

The drug does not affect pulse, blood pressure or urinary output. Its toxicity is extremely low, so that

Fig 4—The action of posterior pituitary extract lasts less than ten minutes and the motility induced by this drug is irregular in character

many times the therapeutic dose causes no undesirable symptoms. Its cumulative action is likewise negligible, since prolonged administration in patients resulted in no signs of toxicity. The drug is colorless, tasteless and odorless and is administered therapeutically with ease. The crystals are entirely stable, so that oral tablets can be kept indefinitely. The aqueous solution, however, is as yet not sufficiently stable. The powder is therefore best dissolved in water just before it is to be administered intravenously.

SOLUTION OF POSTERIOR PITUITARY

Oliver and Schafer¹⁶ in 1895 first prepared an extract of the posterior lobe of the pituitary gland and observed pressor effects on experimental animals. Dale¹⁷ in 1906 demonstrated that the most important pharmacologic action of such an extract was its oxytocic activity. This principle was first applied to the parturient woman three years later by Blair Bell,¹⁸ thereby introducing one of the most important therapeutic agents in obstetrics. Kamm and his co-workers¹⁹ separated the posterior pituitary extract into a fraction containing the oxytocic principle, "pitocin," and one containing the diuretic and pressor principles, "pitressin."

The aqueous extract of the posterior pituitary gland is stable and can be kept almost indefinitely unless exposed to temperatures above 40 C. It is standardized

by a comparison of the response of the excised uterus of the guinea-pigs under standard conditions, with a standard sample of dried posterior pituitary.

The action of posterior pituitary extract in the immediate postpartum period and in the puerperium is quite uniform. Its intramuscular or subcutaneous administration causes the initiation of uterine motility in from three to five minutes. The uterus becomes tetanic, and as the tonus diminishes increasingly vigorous contractions occur. The action of the drug lasts for five or ten minutes and rapidly disappears, to be reinitiated by another dose (fig 4). The intravenous administration of small doses, 3 minims (0.2 cm), provokes an immediate response. However, the general reaction to this mode of therapy is quite marked. The patient may develop a marked circumoral pallor, a sense of constriction in the chest, pain in the back of the head, marked palpitation, nausea and occasionally vomiting. The reaction may last several minutes or longer and gradually disappear without any serious effects.

Posterior pituitary extract has a variable effect on blood pressure of normal individuals. Usually they show little or no elevation of blood pressure after therapeutic doses of posterior pituitary. The pallor which may develop is not an index of a change in blood pressure. However, in patients with hypertension a marked elevation occurs after intravenous or intramuscular administration of the drug. The rise in pressure is transitory and is followed by a return to normal. Posterior pituitary extract also causes a diminution in the urinary output, which likewise becomes more marked in patients with kidney damage. A temporary anuria may occur in patients with toxemia of pregnancy. These abnormally marked effects of pituitary solutions on blood pressure and urinary output in patients exhibiting toxemia of pregnancy make the use of this drug undesirable in this group.

OTHER OXYTOCIC DRUGS

Quinine, an alkaloid derived from cinchona bark, has maintained a wide clinical popularity. It has been used to augment weak, ineffective labor pains but more commonly in conjunction with castor oil for the induction of labor. Its oxytocic action is very mild and unreliable, even though it is administered in doses large enough to evoke a general reaction. It is our impression that quinine does seem to sensitize the pregnant uterus at or near term, so that it becomes more responsive to the more potent oxytocics, posterior pituitary extract and ergonovine. Thus, its use in obstetrics is rather restricted.

Hydrastis has been combined with ergot to augment the oxytocic effect. In large therapeutic doses hydrastis alone does not evoke regular uterine motility or accentuate motility initiated by ergot.

INDICATIONS FOR OXYTOCIC DRUGS

Use in Nonpregnant Patients—The present indications for oxytocics are almost limited to pregnancy and its complications. Although posterior pituitary extract and ergot will cause tonic and contractions of the nonpregnant uterus, they are rarely indicated except for temporary relief of bleeding. All bleeding, whether in the form of profuse or prolonged menses or bleeding between the menstrual periods, should be considered of sufficient pathologic import to merit a careful investigation and a correct diagnosis. It is never justifiable to give oxytocics as a temporary expedient in the hope that the bleeding will cease. Once a diagnosis is positively established ergonovine can be given in the hope

16 Oliver and Schafer, *J. Physiol.* 18:276, 1895.

that bleeding can be temporarily checked. Usually the underlying pathologic condition must be corrected to obtain permanent relief.

Therapeutic Abortion—By medicinal means this is rarely successful. The uterus is poorly responsive to posterior pituitary extract early in pregnancy. Many investigators feel that the corpus luteum of pregnancy inhibits the uterine response to posterior pituitary extract. That this is true in animal experimentation, notably in the rabbit, is borne out by a host of investigators. Less is known about the uterine response to ergot early in pregnancy. Clinical experience justifies the conclusion that it is almost impossible to interrupt the normal gestation early in its course by the known oxytocic drugs.

When normal pregnancy has been interfered with, such as in inevitable or incomplete abortions, the oxytocic drugs can be used to hasten or complete the process. Posterior pituitary extract and ergot can be used to initiate uterine motility or to increase it when already initiated. We have observed the results obtained in a small group of these cases and have found that the new ergot alkaloid has a beneficial effect. In some of the cases the retained secundines were expelled and the hemorrhage was controlled. Following a complete or completed abortion, ergonovine, given orally for several days, is of distinct value to control bleeding and favor normal involution.

Induction of Labor—The medicinal induction of labor becomes more successful the closer to term it is used. At least half the cases can be induced when the induction is tried at term. Before term when induction is indicated because of some complication of pregnancy, medicinal induction must be combined with some mechanical means. The method of medicinal induction of labor at or near term used at the Chicago Lying-in Hospital consists of the following procedure: Castor oil, 1½ ounces (42 cc), is given early in the morning, followed two hours later by quinine in 3 grain (0.2 Gm) doses at hourly intervals for four or five doses, followed by graduated doses of posterior pituitary extract, beginning with half a minim (0.03 cc) and increasing half a minim at each dose fifteen minutes apart until 3 minims (0.2 cc) is given. The latter dose can be repeated until a total of 1 cc is used. The uterus should be carefully observed, and if it exhibits tetanic contractions so that the fetal heart tones are interfered with, the posterior pituitary extract is discontinued. The administration of the drug ceases when regular, rhythmic contractions are initiated anywhere in the course of the induction.

Labor—The oxytocic drugs are rarely indicated during the first and second stages of labor. Although Stearns² first introduced ergot to stimulate labor pains and shorten the course of labor, clinicians soon noted the ill effects of the indiscriminate use of the drug. Ergot soon lost its popularity in labor, and today it has no place in the first and second stages. Posterior pituitary extract is rarely indicated during the first and second stages of labor. It is occasionally administered during this period in cases of uterine inertia in 2 or 3 minim (0.13 or 0.2 cc) doses when the ineffective contractions result in a long painful labor with little or no progress. Its use under such circumstances is fraught with great danger for the patient and her baby. Uterine tetany, abnormal uterine motility, with possible complications at delivery and intra-uterine asphyxia of the baby, are not uncommon sequelae. Rupture of the

uterus³⁰ is a real danger. Because of these untoward complications, posterior pituitary extract as well as ergot must be omitted from the therapeutic regimen of this period of labor.

Posterior pituitary extract can be administered immediately following the birth of the baby to facilitate the third stage of labor. The placental stage can be shortened and hemorrhage decreased by this means. The objection to the routine use at this period of labor is that the drug may cause a contraction zone at the lower uterine segment, resulting in the incarceration of a partially or completely separated placenta. This interference with the normal mechanism of separation and expulsion of the placenta may eventuate in a postpartum hemorrhage. The use of posterior pituitary extract in the third stage of labor should be confined to hospital practice, where complications of the third stage, which may result from its use, can be more safely managed than in the home. It should not be used before the completion of the first phase of this stage or placental separation.

In the immediate postpartum period, hemorrhage due to uterine atony is the most important indication for the use of oxytocics. Postpartum hemorrhage accounts for from 10 to 12 per cent of the maternal deaths that occur every year. It is the complication that is ever before the mind of the obstetric attendant. The rapidity of its onset, its magnitude, the rapid development or the serious symptoms often overwhelm the accoucheur. It is here that oxytocics fulfil their greatest role.

One must remember that uterine atony is not the only cause for postpartum hemorrhage. Trauma of the soft parts such as deep cervical tears and uterine rupture, may lead to serious and even fatal postpartum bleeding, which, needless to say, no oxytocics can control. Portions of placenta retained in the uterus may account for uterine bleeding and interfere with the action of oxytocics. A careful diagnosis of the cause of the hemorrhage must be made to determine the etiology.

Posterior pituitary extract in 1 cc doses subcutaneously or intramuscularly can be given. Small doses, 3 minims or less, can be given intravenously in an emergency regardless of the possible reaction. Ergonovine is the ideal drug and can be given intravenously in 0.2 mg doses for its immediate and sustained action. This drug can likewise be given by mouth if the patient is not under anesthesia.

We have had an opportunity of observing the action of ergonovine in some twenty labors complicated by postpartum hemorrhage. The following brief case summaries will illustrate the spectacular action of this new oxytocic agent.

CASE 1—A primipara aged 20, was admitted to the hospital one and a half hours following home delivery, Jan 13, 1936. The pulse was 150 and the blood pressure 55 systolic 20 diastolic. The placenta was retained in utero and attempts at manual removal at home failed to deliver it. Posterior pituitary extract, 1 cc, had been administered at home for the profuse hemorrhage. Treatment in the hospital consisted of manual removal of the placenta and immediate intravenous administration of 0.2 mg of ergonovine. The uterus contracted firmly and remained so. No further oozing occurred. She received a transfusion of 700 cc of blood and one of 600 cc of 10 per cent dextrose solution.

CASE 2—A quintipara octigravida, aged 28 entered the hospital, Feb 12, 1936 with a transverse presentation. The pulse was 90 and the blood pressure 120 systolic, 80 diastolic. A Voorhees bag was introduced into the uterus and after a

20 Telfair, J. H. *Am. J. Obst.* 73: 655 (April) 1916.
L. G. *ibid.* 74: 432 (Sept.) 1916.

twenty-four hour labor sufficient dilatation and effacement were obtained to deliver the baby by version and extraction. Following the manual removal of the placenta a profuse vaginal hemorrhage occurred as the result of uterine atony. Ergonovine, 0.2 mg intravenously, was followed by immediate contraction of the uterus and cessation of bleeding. The blood loss was 1,000 cc. (measured).

PUERPERIUM

The use of oxytocic drugs in the puerperium has enjoyed almost universal popularity. Ergot in its various forms has been the therapeutic bulwark for this period. It has been credited with hastening normal involution, decreasing the likelihood of late postpartum bleeding, limiting the likely spread of intra-uterine infection if present, and helping to maintain the genital organs in the best state possible. The present study was undertaken to evaluate carefully the therapeutic possibilities of ergot in its most desirable form, ergonovine.

A group of 200 women were placed on ergonovine during their first three days of the puerperium. Careful observations were made of all the factors involved in normal and abnormal involution of the uterus. This group on routine ergot therapy was contrasted with a similar group in which no oxytocic drugs were given.

tion and expulsion of the placental site. When the uterine cavity is again lined by normal endometrium, the uterus has completely reverted to its nonpregnant state. The duration of the process is variable but usually is eight or ten weeks in the normal individual.

The mechanism of involution is as yet unknown, however, many factors influence the process. Metabolic and catabolic processes must play an important role in the physiologic atrophy of the uterus. Uterine tone and motility must likewise have an important bearing. In an experimental study on the physiology of the puerperal uterus, uterine tone and motility were recorded on graphs by the introduction of a small rubber balloon into the uterine cavity.²¹

It was found that immediately following delivery there is considerable tone in all uteri and regular rhythmic contractions occur. By the end of the fifth day of the normal puerperium the majority of primiparas still show considerable tonic and regular uterine motility. However, multiparas vary considerably. About half the patients exhibit no tone or uterine motility, and the small bag may remain in the uterus for several hours without eliciting any response. About 25 per cent of the cases exhibit irregular contractions, spasmodic in character, which may be excited to regularity, increased frequency and amplitude by the uterine bag or by various oxytocic drugs. The remaining cases show regular rhythmic contractions altered little from the onset of the puerperium. Little additional change has occurred by the end of the ninth or tenth day. As all the patients observed in these and subsequent studies were normal, it was difficult to evaluate the effect of uterine motility on delayed or abnormal involution. Clinical observation, however, has given the impression that the boggy, atonic condition of the uterus which does not respond to external stimulation seriously interferes with its normal involution.

The criteria of involutional progress are the extent of atrophy of the uterus, the general consistency of the musculature and its lack of irritability to suitable stimuli, and the character and amount of the lochia. These factors are difficult to evaluate, for they are subject to considerable variation in perfectly normal individuals. However, one can gain definite impressions by careful observations.

A group of normal puerperal women were followed carefully to note the rate of the progressive atrophy of the uterus. The uterine outline was accurately sketched from day to day during their ten day hospital stay. Figure 5 represents reproductions of uterine outlines drawn to scale in representative cases. Needless to say the bladder was empty when each outline was made. From the foregoing one can see that the uterus is always palpable above the symphysis at the tenth postpartum day and that its height averages 4 or 5 cm.

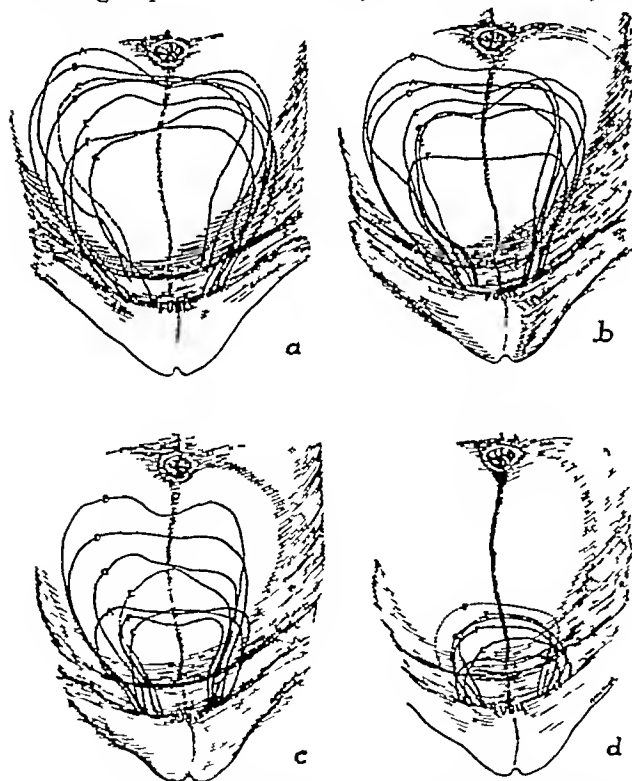

Fig. 5—Normal uterine involution in a series of normal puerperal women of various ages and parity. a first day b fourth day c seventh day and d tenth day.

during the puerperium. The observations and impressions gleaned from this careful investigation are here recorded.

Physiology of Postpartum Involution.—The physiologic process by which the puerperal uterus is reduced to approximately one-twentieth its size and restored to the normal nonpregnant state is known as involution. It involves desquamation and expulsion of the remaining decidua basalis, the decrease of the individual constituent muscle fibers to a fraction of their hypertrophied state, and the ultimate exteriorization, separa-

Fig. 6—A composite diagram to illustrate the uterine involution in a group of 200 women who received ergonovine maleate during the first three days of the puerperium.

above this level. Involution progresses at a much more rapid rate during the first five days than during the second five days. Physiologic uterine atrophy takes place at a progressively diminishing rate.

The group of patients that received ergot in the form of ergonovine exhibited a more rapid decrease in the size of the uterus. Figure 6 is a composite reproduction, drawn to scale, of the uterine outlines of the 200 patients on ergot therapy. This increased rate of involution was most apparent during the last few days of the hospital stay. The rapid return of the uterus to normal size is desirable because a large, heavy uterus probably predisposes to malpositions in the late puerperium.

Improper drainage of lochial secretions due to malpositions of the uterus and to inactivity and the lack of tone on the part of the muscular organ has been said to delay involution. Our work on the postpartum patient has demonstrated that lochial retention is present in almost 25 per cent of the patients. The escape of 25 or 30 cc of retained fluid has been noted in this group of patients when the rubber balloon is introduced for kymographic study. In quite a number of the patients as much as from 100 to 200 cc has escaped. It must be remembered that only normal cases exhibiting no symptoms referable to the retention of lochia were studied. Our puerperal patients are not quiescent but lead a rather active life while confined to bed. Thus frequent changes in posture have not led to satisfactory drainage. Further study of this group has revealed a lack of uterine motility and tone. Stimulation of these patients by oxytocic drugs should favor involution. The actual character of the lochia is probably an unimportant factor in involution.

Infection of the uterus or its appendages seriously delays involution. The uterus remains large, soft, and unresponsive to stimulation. This condition favors the retention of infectious contents in its cavity and favors the spread of infection in the genital organs and to environmental structures. The large thrombosed vessels of the placental site may be incompletely cut off from the circulation, favoring extension of the thrombi and embolic phenomena. Theory and practice have favored the stimulation of tonicity and uterine motility in these circumstances.

Summary of Study on Patients Who Received Ergot and Controls

| | 200 on Ergot Therapy | | 200 Control Cases | |
|--------------------------|----------------------|----------|-------------------|----------|
| | Cases | Per Cent | Cases | Per Cent |
| Morbidity .. | 37 | 18.5 | 53 | 26.5 |
| In hospital over 10 days | 6 | 2.5 | 13 | 6.5 |
| Operative incidence | 54 | 27.0 | 55 | 27.5 |
| Epiliotomies | 150 | 75.0 | 133 | 66.5 |

* Any patient who exhibited a temperature of 38 C (100.4 F) or over on any day after the first twenty-four hours was listed as morbid.

The accompanying table summarizes the data obtained from a study of the group of patients that received ergot during the puerperium and of the control group. These groups are far too small to provide more than a general impression that the increased uterine tonicity and motility resulting from the administration of ergot had a favorable influence on morbidity.

The use of oxytocic drugs in the puerperium²² is of value in aiding involution by increasing uterine tone and increasing or reinitiating uterine motility. Thus

uterine activity results in complete evacuation of the uterine cavity of its lochial secretions, a more rapid decrease in the size of the uterus, and perhaps some limitation of the spread of infection if present. Ergot therapy is therefore of value when involution is not progressing normally because of a lack of uterine tone and motility, because of retained secretions, or in the presence of uterine or general infection. The prophylactic use of ergot to assure a normal involution is probably of some value, although further studies with ergonovine will be necessary to confirm this impression. A careful follow up of patients for six months and longer will ascertain whether the incidence of malpositions is less in patients receiving ergot therapy in the early puerperium.

It has been our practice to prescribe ergot in the puerperium for delayed involution. At present ergonovine maleate,²³ from 0.2 to 0.4 mg three times daily, is given to patients who have had a postpartum hemorrhage, a difficult forceps, intra-uterine manipulation, abnormal lochia, fever regardless of the cause, or delayed involution without cause. This therapy is kept up for at least three days or as long as is necessary. If uterine contractions become too painful, the dose of ergonovine maleate is reduced or the drug omitted.

HYPERVENTILATION IN ABDOMINAL SURGERY

THOMAS J. RYAN, M.D.

PHILADELPHIA

Abdominal operations are associated with a very much higher incidence of pneumonia, embolism and atelectasis than extra-abdominal procedures, and many theories regarding the method of their production have been advanced. Muller, Overholt and Pendergrass¹ have shown that hypoventilation, diminished vital capacity and subsequent compression of the bases of the lungs occur after practically all upper abdominal operations, and that these conditions were the result of elevation of the diaphragm and reduction in the normal diaphragmatic excursions, as shown by x-ray studies. Graham, in a discussion of this paper, referred to the value of carbon dioxide inhalations on the operating table for the reduction of the incidence of pulmonary complications.

On the assumption that the entrance of air into the abdominal cavity might be instrumental in causing the elevation of the diaphragm and limitation of its excursions, this investigation was undertaken to determine the value of inhalations of carbon dioxide during closure of the abdominal cavity, and at the same time to report the incidence of pulmonary complications occurring at the Misericordia and Fitzgerald-Mercy hospitals. The study began Nov. 1, 1934, and was continued until June 1, 1935. The patients were admitted to the surgical services of Drs. Beltran, Kelly, Muller and myself. The group comprises 411 abdominal operations. Carbon dioxide was administered until deep respiration was produced. The amount was variable, the average being a 10 per cent mixture of carbon dioxide with oxygen, given for about three

²³ Ergotrate is the trade name of ergonovine maleate (Lilly) which was used in our experimental and clinical observations.

Read before the Philadelphia Academy of Surgery Oct. 7, 1935.

minutes. Care was taken not to tire the patient unduly or to raise the blood pressure excessively. Of the 411 patients admitted, 135 received this treatment during the process of closure of the abdominal cavity.

Early in our experience my associates and I were impressed with the ability of this gas to deoxygenize the patient, as reported by White,² and to improve the blood pressure, as reported by Henderson.³ In addition to the inhalation of carbon dioxide in the operating room we advised all abdominal patients to expand the lungs by deep breathing during the immediate postoperative stage, as suggested by Scott.⁴

Henderson,⁵ in one of his contributions, concludes that the "inhalation of carbon dioxide, by counteracting

bronchial secretion was removed from a patient suffering from atelectasis. This substance was injected into the main bronchus of a dog, producing massive atelectasis, which was completely relieved after aspiration of the mucus. These experiments are the only conclusive data submitted to date on the etiology and cure of this condition.

Scott and Cutler⁹ believe that atelectasis is initiated by a nervous reflex probably largely vasomotor, which results in a narrowing of the lumen in the peripheral bronchioles by venous engorgement, swelling of the mucous membrane, and the elaboration of a tenacious secretion.

In our efforts to secure a comparable group of cases we included all patients on whom abdominal operations were performed. In order to have the conditions identical, the two groups were simultaneously conducted. Table 1 shows the varied types of operations that were performed.

It will be noted that appendectomy, for both acute and chronic conditions, was performed on 187 patients and was associated with five pulmonary complications, a most striking feature being the fact that four occurred in patients who were operated on for acute appendicitis. This is in keeping with the observation of King,¹⁰ namely, the incidence of pulmonary complications is markedly increased in operations that are performed in an already infected area. The group of ninety-three cases under the heading of gynecology included all types of pelvic operations in which it was necessary to open the abdominal cavity. There were no pulmonary complications, although thirteen operations were performed for chronic pelvic inflammatory disease.

The operations on the colon consisted of colostomy and resection of the colon for carcinoma and were not attended with any major pulmonary complication. The twenty-three operations on the stomach were practically

TABLE 1—Group of 411 Abdominal Operations

acapnia and inducing deeper breathing, inflates the lungs and prevents the development of atelectasis, thus becoming a specific preventive of the postoperative pulmonary complications that lead to pneumonia."

Cutler,⁶ in discussing postoperative complications, concludes that in view of the evidence now at hand embolism certainly plays a rôle in many of these pulmonary complications, and for this reason everything possible should be done to avoid spreading infection and to handle tissues with the utmost care. Such procedures as the proper ligation of an open vein or, better still, the placing of clamps on all vessels before division so that tissue juices and bacteria do not enter such channels, are of major importance. The only thing in common to all surgical patients is the wound, and it behooves surgeons to look there for postoperative difficulties and not lay the blame for such sequelae on extraneous matters.

In September 1925 Lee⁷ was the first to suggest any form of treatment that had a favorable effect on fully established atelectasis. In collaboration with Jackson, bronchoscopic aspiration in several cases produced sufficient improvement in the patient's condition and the degree of atelectasis to establish this as an accepted form of therapy. Other papers by Lee have materially increased interest in the management of this severe postoperative complication, especially the animal experiments of Lee and Tucker,⁸ wherein very thick tenacious

TABLE 2—Pulmonary Complications in 411 Abdominal Operations

| Name | Age | Diagnosis | Complication | Carbon Dioxide | Result |
|-------|-----|----------------------|------------------------|----------------|-----------|
| L. G. | 51 | Acute appendicitis | Bronchopneumonia | Yes | Recovered |
| J. T. | 41 | Acute appendicitis | Empyema | No | Died |
| M. M. | 34 | Acute appendicitis | Pleurisy with effusion | Yes | Recovered |
| T. R. | 44 | Acute appendicitis | Embolism, right | No | Recovered |
| M. M. | 31 | Acute cholecystitis | Atelectasis, right | No | Recovered |

| A. F. | 69 | Chronic pancreatitis | Embolism, right | Yes | Died |

all gastro-enterostomies. Although this operation should be associated with a high incidence of complication, none occurred.

Herniorrhaphy carries a higher incidence of pulmonary complications than is apparently justified by the severity of the operative procedure. Since this operation is always done in a clean area and there is very little motion of the abdominal wall in this region, it is difficult to assign a single etiologic factor for the production of complications in the lungs.

Of the thirty-seven gallbladder cases, two pulmonary complications occurred. Cholecystectomy was performed in twenty-three patients for chronic and on three patients for acute conditions. Cholecystostomy was performed for acute cholecystitis on six patients and for chronic pathologic processes on five. The operations on the small intestine included resection, enterostomy and adhesions. Although the group was small there were no complications.

Table 2 is a summary of the complications described. It should be noted that five occurred following operations for acute pathologic conditions, while two resulted from operations that were performed for chronic processes.

REPORT OF CASES

CASE 1—L. G., a woman, aged 51, was admitted to the Misericordia Hospital Feb 24, 1935, with generalized peritonitis and maximum pain over the gallbladder. Operation was deferred for eight hours in order to promote localization of the process, as well as to make the diagnosis more definite. At the time of operation, tenderness and rigidity were localized over the right lower quadrant. The abdomen was opened through a low right rectus incision, and a large quantity of pus and a ruptured appendix were removed. Drainage was instituted. On the second postoperative day bronchopneumonia developed, which was verified by x-ray examination. A complete recovery occurred and the patient was discharged after eighteen days. Carbon dioxide was given during the process of closure of the abdominal cavity.

CASE 2—J. T., a boy, aged 4, was admitted to the Misericordia Hospital Jan 10, 1935, with an appendiceal abscess and a gangrenous appendix, which was removed. He was readmitted to the hospital February 4 with a secondary abscess in the left lower quadrant of the abdomen, which was excised and drained. One week after the second operation, evidence of pleural effusion occurred and positive blood culture for hemolytic streptococcus was secured. Aspiration of the chest revealed pus, and a rib resection was performed. Death occurred sixteen days after admission. The patient was not given carbon dioxide.

CASE 3—M. M., a woman, aged 41, was admitted to the Misericordia Hospital April 14, 1935, and operation revealed a generalized peritonitis with a perforated appendix. Drainage was instituted. One week after operation the patient developed acute pain over the posterior aspect of the right chest, followed by effusion of clear fluid, which was removed by aspiration. A complete recovery ensued. Carbon dioxide was given for three minutes during closure of the abdominal cavity.

CASE 4—T. R., a man, aged 44, was admitted to the Misericordia Hospital April 12, 1935, and was operated on for a localized peritonitis and an acutely inflamed gangrenous appendix, which was removed. Drainage was instituted. Ten days after operation the patient suffered from an acute pain in the right side of the chest. A diagnosis of pulmonary embolism was made. X-ray examination of the chest revealed a small area of consolidation in the right lobe. The patient made a complete recovery. Carbon dioxide was not given.

CASE 5—M. M., a woman, aged 31, was admitted to the Misericordia Hospital March 31, 1935, with a diagnosis of acute cholecystitis and chronic appendicitis. The gallbladder and appendix were removed. On the second postoperative day lobular pulmonary atelectasis occurred, which was verified by x-ray examination. A complete recovery ensued with postural drainage. Carbon dioxide was not given during closure of the abdominal cavity.

CASE 6—A. N., a boy, aged 15, was operated on for chronic appendicitis. The operation was performed without any complications or difficulties. On the day following operation, collapse of the left lung occurred. Relief was obtained by postural drainage. The patient made a complete recovery. No carbon dioxide was given.

CASE 7—A. F., a woman, aged 69, was admitted to the Misericordia Hospital Feb 11, 1935, with an elevated temperature and a white blood count of 13,000. She also had jaundice and pain over the gallbladder. After five days a cholecystos-

tomy was performed and the operation revealed a contracted gallbladder with acute inflammatory reaction in the common duct and enlargement of the pancreas. Although the final diagnosis was chronic cholecystitis and pancreatitis, there were some evidences in the case of acute inflammation. During the following two weeks her temperature was continually above normal. March 3 she expectorated bloody mucus which was diagnosed as embolus by physical signs. March 9 the patient died. Carbon dioxide had been given.

COMMENT

The group of 135 cases in which carbon dioxide was given, as shown in table 3, was associated with three pulmonary complications, including bronchopneumonia, pleurisy with effusion, and embolism. One of the patients died and two recovered, making a pulmonary morbidity of 2.2 per cent and a pulmonary mortality of 0.74 per cent. Carbon dioxide was not given to 276 patients. In four cases, which included empyema, embolism and two cases of atelectasis, pulmonary complications occurred, making a morbidity of 1.4 per cent and a mortality of 0.36 per cent.

In a personal communication Dr. E. C. Cutler suggested that comparable cases be used for the study. In following out this plan it was found that of the 124 cases diagnosed as acute appendicitis carbon dioxide was given in thirty-three and not given in ninety-one,

TABLE 3—Group of 411 Abdominal operations

| | Carbon Dioxide | No. of Cases | Pulmonary Morbidity | Pulmonary Mortality |
|-----------|----------------|--------------|---------------------|---------------------|
| Given | | 135 | 2.2% | 0.74% |
| Not given | | 276 | 1.4% | 0.36% |
| Total | | 411 | 1.7% | 0.48% |

making an incidence of 6 per cent pulmonary complications in the former group and 2 per cent in the latter. Of the sixty-three patients diagnosed as having chronic appendicitis, seventeen received carbon dioxide and forty-six did not, resulting in no pulmonary complications for the former and one case of collapse in the latter. Under gallbladder surgery there were thirty-seven cases, in seven of which carbon dioxide was given, and in thirty not given, making an incidence of 14 per cent for the former and 3.3 per cent for the latter.

CONCLUSIONS

1. A study was made of 411 abdominal operations to determine the value of carbon dioxide inhalations during closure of the abdomen.

2. It would appear from this study that carbon dioxide is of no value in the prevention of postoperative pneumothorax.

3. This group of cases accentuates the importance of infection in the operative field as an etiologic factor in the production of postoperative pulmonary complications.

Vitamin in Salmon Oil—The salmon, on the other hand, is a fat fish, it has much body fat and its store of fat-soluble vitamin is not contained in its liver only but in the fat of its body as a whole. The concentration of vitamin in salmon oil is therefore not usually so high as in the liver oil of a much leaner fish, but the total amount of fat-soluble vitamin furnished by salmon (fresh and canned) is quite large.—Sherman, Henry C. Food and Health, New York, Macmillan Company, 1934.

MORTALITY OF NEW-BORN INFANTS
IN CHICAGO DURING 1935

WITH SPECIAL REFERENCE TO THE PREMATURE

CHICAGO

Survey of Deaths of Infants Under 30 Days of Age

—In order to determine ways of further decreasing infant mortality in Chicago during 1935, the Board of Health made an intensive field investigation of the deaths of every infant aged 30 days or less. A questionnaire was devised covering sixty-eight items relating to the prenatal period, the process of delivery, and postnatal care. This questionnaire served as a framework on which the whole structure of the inquiry was built and developed.

Table 1 presents the details concerning the birth rates, stillbirth rates, and infant mortality rates in Chicago for the period from 1925 to 1935 inclusive, showing especially the rates for deaths under 1 month and from 1 month to 12 months. The accuracy of calculation of infant mortality rates on the basis of

TABLE 1—*Birth Rates, Stillbirth Rates and Infant Mortality in Chicago 1925-1935*

| Year | Total Live Births | Stillbirths | | Total Deaths Under One Year of Age | | Deaths Under One Month | | Deaths One to Twelve Months | | Births per 1,000 Total Population |
|------|-------------------|-------------|-------|------------------------------------|-------|------------------------|-------|-----------------------------|-------|-----------------------------------|
| | | Num | Rate* | Num | Rate* | Num | Rate* | Num | Rate* | |
| 1925 | 60,679 | 2,193 | 36.9 | 4,457 | 74.7 | 2,268 | 37.0 | 2,249 | 37.7 | 19.5 |
| 1926 | 60,290 | 2,242 | 37.2 | 4,007 | 66.6 | 2,067 | 34.3 | 1,940 | 32.2 | 19.8 |
| 1927 | 60,848 | 2,214 | 36.4 | 3,822 | 62.7 | 2,109 | 34.6 | 1,713 | 28.1 | 19.6 |
| 1928 | 60,016 | 2,200 | 37.3 | 3,763 | 63.0 | 2,049 | 34.7 | 1,716 | 29.1 | 18.7 |
| 1929 | 59,900 | 2,142 | 36.4 | 3,333 | 60.1 | 2,030 | 34.5 | 1,503 | 26.6 | 18.4 |
| 1930 | 58,083 | 2,072 | 35.7 | 3,102 | 53.4 | 1,789 | 30.8 | 1,313 | 22.6 | 17.2 |
| 1931 | 62,973 | 1,006 | 36.0 | 2,957 | 56.4 | 1,692 | 31.4 | 1,323 | 20.0 | 15.3 |
| 1932 | 49,248 | 1,535 | 31.2 | 2,404 | 48.8 | 1,467 | 29.8 | 937 | 19.0 | 14.0 |
| 1933 | 46,633 | 1,403 | 30.1 | 2,278 | 48.8 | 1,454 | 31.2 | 824 | 17.7 | 13.0 |
| 1934 | 47,935 | 1,399 | 29.2 | 2,289 | 47.7 | 1,451 | 30.0 | 838 | 16.8 | 13.7 |
| 1935 | 49,425 | 1,325 | 26.9 | 1,933 | 40.1 | 1,361 | 27.5 | 622 | 12.6 | 14.2 |

* Per thousand live births

the number of reported deaths under 1 year per thousand live births is dependent among other things, on the completeness of registration of births and deaths. In Chicago a survey carried out by the United States Census Bureau during 1935 showed that there was 99.5 per cent registration of births. It should be noted that the stillbirth rate also has been declining during the period from 1925 to 1935 inclusive. This fact would seem to indicate that the decreasing number of infant deaths cannot be explained as due to a tendency to classify, as stillbirths, infants born alive but dying soon after birth.

During 1935 the Board of Health adopted a number of measures which had been found to be successful in reducing premature deaths at Sarah Morris Hospital.¹ It was felt that establishing the same methods throughout the city at large would aid somewhat in reducing the mortality during the first year of life, especially of

premature infants, as well as reducing the number of stillbirths. At the same time the program of infant care which had been instituted before 1935 was continued and enlarged.

At present the program of care for all infants under 2 years of age, including the premature, is as follows:

As soon as a birth is registered, the book "Our Babies," describing in simple language with many illustrations, the details of infant care, is sent to the mother, and a Board of Health nurse makes a birth registration call at the home, delivering a birth certificate and the first of a series of monthly letters on infant care.

The nurse urges the mother to keep the baby under a private physician's care but if the mother cannot afford a private physician she is urged to register the infant at one of the twenty-eight Board of Health infant welfare stations or one of the eighteen stations conducted by the Infant Welfare Society of Chicago, depending on the district in which she lives. Each month one of the pamphlets on infant care is sent to the mother. These monthly pamphlets give the important things to be done for the baby each month.

The nurse keeps in touch with the infants who are under the care of private physicians, to make sure that these babies are taken to their doctors regularly. Those not under the care of private doctors and not registered at the welfare stations are visited monthly by the nurse, who at each visit continues to urge medical supervision. If a baby is sick or the home conditions are poor, she makes daily visits to see that the infant is getting proper care and medical attention. If a baby is registered at one of the stations it is the responsibility of the station nurse to see that he continues to be brought to the station. All nurses have a panel of cards (one card for each baby in the district), which enables them to keep track of these babies and permits the supervisors to keep a definite check on the progress of the work. A copy of this card is shown herewith.

Whenever a nurse finds a baby in urgent need of medical care, or whenever home conditions are not adequate for good infant care, every possible effort is made to have the child hospitalized.

Another measure taken during 1935 was the adoption of standardized rules for the care of new-born and premature infants in hospitals. These rules and regulations were sent to all the hospitals and, as a result, improvement in hospital facilities and procedure has resulted as determined by Board of Health surveys made before and after their passage. These surveys were carried out by a nurse with many years of experience as a nurse in one of Chicago's largest hospitals. Regulations for obstetric care were also adopted.

During 1935, of the 1,361 infants who died under 30 days of age, 795 or 58.4 per cent, were considered to be premature, that is they were of less than eight and a half months' gestation and were regarded as premature by the physician. Eighty-four and eight-tenths per cent weighed less than 5 pounds. In 450 instances prematurity alone was given as the cause of death on the death certificate while in the other 345 cases there were other causes of death besides the prematurity. It is obvious then, that one of the most promising fields of endeavor for the further reduction of infant mortality lies in an effort to save the lives of premature infants.

It has been pointed out by a number of observers² that, for the premature infant who has any possibility of surviving, the chances of living can be improved by keeping the baby warm enough from the moment of birth, by giving adequate and proper food, that is, breast milk (or the best possible substitute), by preventing infections, and by giving intelligent nursing and medical care.
